Internal problem ID [8139]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 1
Date solved : `Monday, October 21, 2024 at 04:54:20 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(x^2-1\right) y''-2xy'+2y=0$$

1.1.1 Solved as second order ode using Kovacic algorithm

Time used: 0.221 (sec)

Writing the ode as

$$\left(x^2-1\right) y''-2xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-1 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{(x^2 - 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= (x^2 - 1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{(x^2 - 1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 1: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x+1)^2} + \frac{3}{4(x+1)} - \frac{3}{4(x-1)} + \frac{3}{4(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{\left(x^2 - 1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
-1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\,(x-1)} + \frac{3}{2\,(x+1)} + (-)\,(0) \\
&= -\frac{1}{2\,(x-1)} + \frac{3}{2\,(x+1)} \\
&= \frac{x-2}{x^2-1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\,(x-1)} + \frac{3}{2\,(x+1)}\right)(0) + \left(\left(\frac{1}{2\,(x-1)^2} - \frac{3}{2\,(x+1)^2}\right) + \left(-\frac{1}{2\,(x-1)} + \frac{3}{2\,(x+1)}\right)^2 - \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)} + \frac{3}{2(x+1)}\right) dx} \\ &= \frac{(x+1)^{3/2}}{\sqrt{x-1}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2-1}\, dx} \\ &= z_1 e^{\frac{\ln(x-1)}{2} + \frac{\ln(x+1)}{2}} \\ &= z_1\left(\sqrt{x-1}\,\sqrt{x+1}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (x+1)^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2-1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x-1)+\ln(x+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{x\,\mathrm{e}^{\ln(x-1)+\ln(x+1)}}{(x+1)^3 (x-1)}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((x+1)^2\right) + c_2\left((x+1)^2 \left(-\frac{x\,\mathrm{e}^{\ln(x-1)+\ln(x+1)}}{(x+1)^3 (x-1)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.1.2 Maple step by step solution

Let's solve
$(x^2-1)\left(\frac{d}{dx}y'\right) - 2xy' + 2y = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d}{dx}y'$
- Isolate 2nd derivative
  $\frac{d}{dx}y' = -\frac{2y}{x^2-1} + \frac{2xy'}{x^2-1}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d}{dx}y' - \frac{2xy'}{x^2-1} + \frac{2y}{x^2-1} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{2x}{x^2-1}, P_3(x) = \frac{2}{x^2-1}\right]$
  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$
    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = -1$
  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$$\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$$

- $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d}{dx}y'\right) - 2xy' + 2y = 0$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^2-2u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (-2u+2)\left(\frac{d}{du}y(u)\right) + 2y(u) = 0$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

  $$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

  Rewrite ODE with series expansions

  $$-2a_0 r(-2+r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)(k+r-1) + a_k(k+r-1)(k+r-2)\right)u^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $\left((-2k-2r-2)\,a_{k+1} + a_k(k+r-2)\right)(k+r-1) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = \frac{a_k(k+r-2)}{2(k+1+r)}$

- Recursion relation for $r = 0$; series terminates at $k = 2$

  $a_{k+1} = \frac{a_k(k-2)}{2(k+1)}$

- Apply recursion relation for $k = 0$

  $a_1 = -a_0$

- Apply recursion relation for $k = 1$

  $a_2 = -\frac{a_1}{4}$

- Express in terms of a_0

  $a_2 = \frac{a_0}{4}$

- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

  $y(u) = a_0 \cdot \left(1 - u + \frac{1}{4}u^2\right)$

- Revert the change of variables $u = x + 1$

  $\left[y = \frac{a_0(x-1)^2}{4}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k k}{2(k+3)}$

- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k k}{2(k+3)}\right]$

- Revert the change of variables $u = x + 1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x+1)^{k+2}, a_{k+1} = \frac{a_k k}{2(k+3)}\right]$

- Combine solutions and rename parameters

  $\left[y = \frac{a_0(x-1)^2}{4} + \left(\sum_{k=0}^{\infty} b_k (x+1)^{k+2}\right), b_{k+1} = \frac{b_k k}{2(k+3)}\right]$

$$y(x) \to \frac{\sqrt{x^2-1}(c_1(x-1)^2 + c_2 x)}{\sqrt{1-x^2}}$$

1.2 problem 2

Internal problem ID [8140]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 2
Date solved : `Monday, October 21, 2024 at 04:54:21 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(x^2-1\right)y''-6xy'+12y=0$$

1.2.1 Solved as second order ode using Kovacic algorithm

Time used: 0.223 (sec)

Writing the ode as

$$\left(x^2-1\right)y''-6xy'+12y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-1 \\ B &= -6x \\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{15}{(x^2 - 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15 \\ t &= (x^2 - 1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15}{(x^2 - 1)^2} \right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 3: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 0 \\
&= 4
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{15}{4(x-1)} + \frac{15}{4(x+1)} + \frac{15}{4(x-1)^2} + \frac{15}{4(x+1)^2}
$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15}{\left(x^2-1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
-1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{3}{2\,(x-1)} + \frac{5}{2\,(x+1)} + (-)\,(0) \\ &= -\frac{3}{2\,(x-1)} + \frac{5}{2\,(x+1)} \\ &= \frac{x-4}{x^2-1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{2(x-1)} + \frac{5}{2(x+1)}\right)(0) + \left(\left(\frac{3}{2(x-1)^2} - \frac{5}{2(x+1)^2}\right) + \left(-\frac{3}{2(x-1)} + \frac{5}{2(x+1)}\right)^2 - \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(-\frac{3}{2(x-1)} + \frac{5}{2(x+1)}\right) dx} \\
&= \frac{(x+1)^{5/2}}{(x-1)^{3/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6x}{x^2-1}\, dx} \\
&= z_1 e^{\frac{3\ln(x-1)}{2} + \frac{3\ln(x+1)}{2}} \\
&= z_1 \left((x-1)^{3/2} (x+1)^{3/2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = (x+1)^4$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6x}{x^2-1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3\ln(x-1)+3\ln(x+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{x(x^2+1)\,\mathrm{e}^{3\ln(x-1)+3\ln(x+1)}}{(x+1)^7\,(x-1)^3} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((x+1)^4\right) + c_2\left((x+1)^4 \left(-\frac{x(x^2+1)\,\mathrm{e}^{3\ln(x-1)+3\ln(x+1)}}{(x+1)^7\,(x-1)^3} \right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.2.2 Maple step by step solution

Let's solve

$(x^2-1)\left(\frac{d}{dx}y'\right) - 6xy' + 12y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{12y}{x^2-1} + \frac{6xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{6xy'}{x^2-1} + \frac{12y}{x^2-1} = 0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{6x}{x^2-1}, P_3(x) = \frac{12}{x^2-1}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = -3$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$$\left((x+1)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d}{dx}y'\right) - 6xy' + 12y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (-6u+6)\left(\frac{d}{du}y(u)\right) + 12y(u) = 0$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

  - Shift index using $k->k+1-m$

    $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

  - Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

    $$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

  - Shift index using $k->k+2-m$

    $$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

  Rewrite ODE with series expansions

  $$-2a_0 r(-4+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)(k+r-3) + a_k(k+r-3)(k+r-4)\right) u^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(-4+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 4\}$

- Each term in the series must be 0, giving the recursion relation

  $\left((-2k-2r-2)\, a_{k+1} + a_k(k+r-4)\right)(k+r-3) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = \frac{a_k(k+r-4)}{2(k+1+r)}$

- Recursion relation for $r = 0$; series terminates at $k = 4$

  $a_{k+1} = \frac{a_k(k-4)}{2(k+1)}$
- Apply recursion relation for $k = 0$

  $a_1 = -2a_0$
- Apply recursion relation for $k = 1$

  $a_2 = -\frac{3a_1}{4}$
- Express in terms of a_0

  $a_2 = \frac{3a_0}{2}$
- Apply recursion relation for $k = 2$

  $a_3 = -\frac{a_2}{3}$
- Express in terms of a_0

  $a_3 = -\frac{a_0}{2}$
- Apply recursion relation for $k = 3$

  $a_4 = -\frac{a_3}{8}$
- Express in terms of a_0

  $a_4 = \frac{a_0}{16}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

  $y(u) = a_0 \cdot \left(1 - 2u + \frac{3}{2}u^2 - \frac{1}{2}u^3 + \frac{1}{16}u^4\right)$
- Revert the change of variables $u = x + 1$

  $\left[y = \frac{a_0(x-1)^4}{16}\right]$
- Recursion relation for $r = 4$

  $a_{k+1} = \frac{a_k k}{2(k+5)}$
- Solution for $r = 4$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+4}, a_{k+1} = \frac{a_k k}{2(k+5)}\right]$
- Revert the change of variables $u = x + 1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x+1)^{k+4}, a_{k+1} = \frac{a_k k}{2(k+5)}\right]$
- Combine solutions and rename parameters

  $\left[y = \frac{a_0(x-1)^4}{16} + \left(\sum_{k=0}^{\infty} b_k (x+1)^{k+4}\right), b_{k+1} = \frac{b_k k}{2(k+5)}\right]$

1.3 problem 3

Internal problem ID [8141]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 3
Date solved : `Monday, October 21, 2024 at 04:54:22 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+3\right) y''-7xy'+16y=0$$

1.3.1 Solved as second order ode using Kovacic algorithm

Time used: 0.433 (sec)

Writing the ode as

$$\left(x^2+3\right) y''-7xy'+16y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+3 \\ B &= -7x \\ C &= 16 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^2 - 234}{4\left(x^2 + 3\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2 - 234 \\ t &= 4\left(x^2 + 3\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^2 - 234}{4\left(x^2 + 3\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 5: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+3)^2$. There is a pole at $x = i\sqrt{3}$ of order 2. There is a pole at $x = -i\sqrt{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{77}{16\left(x - i\sqrt{3}\right)^2} + \frac{77}{16\left(x + i\sqrt{3}\right)^2} + \frac{79i\sqrt{3}}{48\left(x - i\sqrt{3}\right)} - \frac{79i\sqrt{3}}{48\left(x + i\sqrt{3}\right)}
$$

For the pole at $x = i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{77}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{4}
\end{aligned}
$$

For the pole at $x = -i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x + i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{77}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 234}{4\left(x^2+3\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 - 234}{4\left(x^2+3\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$i\sqrt{3}$	2	0	$\frac{11}{4}$	$-\frac{7}{4}$
$-i\sqrt{3}$	2	0	$\frac{11}{4}$	$-\frac{7}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{7}{2}\right) \\
&= 4
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{7}{4\left(x - i\sqrt{3}\right)} - \frac{7}{4\left(x + i\sqrt{3}\right)} + (-)(0) \\
&= -\frac{7}{4\left(x - i\sqrt{3}\right)} - \frac{7}{4\left(x + i\sqrt{3}\right)} \\
&= -\frac{7x}{2x^2 + 6}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12x^2 + 6x a_3 + 2a_2\right) + 2\left(-\frac{7}{4\left(x - i\sqrt{3}\right)} - \frac{7}{4\left(x + i\sqrt{3}\right)} \right) \left(4x^3 + 3x^2 a_3 + 2x a_2 + a_1\right) + \left(\left(\frac{7}{4\left(x - i\sqrt{3}\right)^2} \right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{ a_0 = \frac{27}{8}, a_1 = 0, a_2 = -9, a_3 = 0 \right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 9x^2 + \frac{27}{8}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^4 - 9x^2 + \frac{27}{8}\right) \mathrm{e}^{\int \left(-\frac{7}{4\left(x - i\sqrt{3}\right)} - \frac{7}{4\left(x + i\sqrt{3}\right)}\right) dx} \\
&= \left(x^4 - 9x^2 + \frac{27}{8}\right) \frac{1}{\left(\left(i\sqrt{3} - x\right)\left(x + i\sqrt{3}\right)\right)^{7/4}} \\
&= \frac{8x^4 - 72x^2 + 27}{8\left(-x^2 - 3\right)^{7/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-7x}{x^2+3} \, dx} \\
&= z_1 e^{\frac{7 \ln\left(x^2+3\right)}{4}} \\
&= z_1 \left(\left(x^2 + 3\right)^{7/4}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \left(\frac{1}{2} + \frac{i}{2}\right) \sqrt{2} \left(x^4 - 9x^2 + \frac{27}{8}\right)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-7x}{x^2+3} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{7 \ln\left(x^2+3\right)}{2}}}{(y_1)^2} \, dx \\
&= y_1 (\text{Expression too large to display})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(\frac{1}{2}+\frac{i}{2}\right)\sqrt{2}\left(x^4 - 9x^2 + \frac{27}{8}\right)\right) \\
&\quad + c_2\left(\left(\frac{1}{2}+\frac{i}{2}\right)\sqrt{2}\left(x^4 - 9x^2 + \frac{27}{8}\right)\text{(Expression too large to display)}\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.4 problem 4

Internal problem ID [8142]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 4
Date solved : `Monday, October 21, 2024 at 04:54:23 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(x^{2}-1\right) y''+8 x y'+12 y = 0$$

1.4.1 Solved as second order ode using Kovacic algorithm

Time used: 0.204 (sec)

Writing the ode as

$$\left(x^{2}-1\right) y''+8 x y'+12 y = 0 \tag{1}$$
$$A y''+B y'+C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{2}-1\\ B &= 8 x\\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2 A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{8}{(x^2 - 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 8$$
$$t = (x^2 - 1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{8}{(x^2 - 1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 6: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{x-1} + \frac{2}{(x-1)^2} + \frac{2}{(x+1)^2} + \frac{2}{x+1}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{8}{\left(x^2-1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	2	-1
-1	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x-1} + \frac{2}{x+1} + (-)(0) \\ &= -\frac{1}{x-1} + \frac{2}{x+1} \\ &= \frac{x-3}{x^2-1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x-1} + \frac{2}{x+1}\right)(0) + \left(\left(\frac{1}{(x-1)^2} - \frac{2}{(x+1)^2}\right) + \left(-\frac{1}{x-1} + \frac{2}{x+1}\right)^2 - \left(\frac{8}{(x^2-1)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{x-1} + \frac{2}{x+1}\right) dx} \\ &= \frac{(x+1)^2}{x-1} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{8x}{x^2-1}\, dx} \\ &= z_1 e^{-2\ln(x-1) - 2\ln(x+1)} \\ &= z_1 \left(\frac{1}{(x-1)^2 (x+1)^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{(x-1)^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8x}{x^2-1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4\ln(x-1)-4\ln(x+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{(x+1)\,(3x^2+1)\,(x-1)^4\,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{(x-1)^3} \right) + c_2 \left(\frac{1}{(x-1)^3} \left(-\frac{(x+1)\,(3x^2+1)\,(x-1)^4\,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.4.2 Maple step by step solution

Let's solve

$(x^2-1)\left(\frac{d}{dx}y'\right) + 8xy' + 12y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{12y}{x^2-1} - \frac{8xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{8xy'}{x^2-1} + \frac{12y}{x^2-1} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{8x}{x^2-1}, P_3(x) = \frac{12}{x^2-1}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left.((x+1)\cdot P_2(x))\right|_{x=-1} = 4$

- $(x+1)^2 \cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d}{dx}y'\right) + 8xy' + 12y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (8u-8)\left(\frac{d}{du}y(u)\right) + 12y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0 r(3+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)(k+r+4) + a_k(k+r+4)(k+r+3)\right) u^{k+r}\right) =$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-3, 0\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r+4)\left((-2k-2r-2)\, a_{k+1} + a_k(k+r+3)\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r+3)}{2(k+1+r)}$

- Recursion relation for $r = -3$

  $a_{k+1} = \frac{a_k k}{2(k-2)}$

- Series not valid for $r = -3$, division by 0 in the recursion relation at $k = 2$

  $a_{k+1} = \frac{a_k k}{2(k-2)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k(k+3)}{2(k+1)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k+3)}{2(k+1)}\right]$

- Revert the change of variables $u = x + 1$

  $\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+1} = \frac{a_k(k+3)}{2(k+1)}\right]$

1.5 problem 5

Internal problem ID [8143]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 5
Date solved : `Monday, October 21, 2024 at 04:54:24 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3y'' + xy' - 4y = 0$$

1.5.1 Solved as second order ode using Kovacic algorithm

Time used: 0.246 (sec)

Writing the ode as

$$3y'' + xy' - 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3 \\ B &= x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 54}{36} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 54 \\ t &= 36 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{36} + \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 8: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{6} + \frac{9}{2x} - \frac{243}{4x^3} + \frac{6561}{4x^5} - \frac{885735}{16x^7} + \frac{33480783}{16x^9} - \frac{2711943423}{32x^{11}} + \frac{115063885233}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{36}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2+54}{36} \\ &= Q + \frac{R}{36} \\ &= \left(\frac{x^2}{36}+\frac{3}{2}\right) + (0) \\ &= \frac{x^2}{36}+\frac{3}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{3}{2}\right) - (0) \\ &= \frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{6} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{3}{2}}{\frac{1}{6}} - 1\right) &&= 4 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{3}{2}}{\frac{1}{6}} - 1\right) &&= -5 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{36}+\frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{6}$	4	-5

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 4$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 4 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x}{6}\right) \\ &= \frac{x}{6} \\ &= \frac{x}{6} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(\frac{x}{6}\right)\left(4x^3 + 3x^2a_3 + 2xa_2 + a_1\right) + \left(\left(\frac{1}{6}\right) + \left(\frac{x}{6}\right)^2 - \left(\frac{x^2}{36} + \frac{3}{2}\right)\right) = 0$$

$$-\frac{a_3x^3}{3} + \frac{2(18 - a_2)\,x^2}{3} + (-a_1 + 6a_3)\,x - \frac{4a_0}{3} + 2a_2 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 27, a_1 = 0, a_2 = 18, a_3 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 + 18x^2 + 27$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^4 + 18x^2 + 27\right) \mathrm{e}^{\int \frac{x}{6} dx} \\
&= \left(x^4 + 18x^2 + 27\right) \mathrm{e}^{\frac{x^2}{12}} \\
&= \left(x^4 + 18x^2 + 27\right) \mathrm{e}^{\frac{x^2}{12}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x}{3} \, dx} \\
&= z_1 e^{-\frac{x^2}{12}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x^2}{12}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^4 + 18x^2 + 27$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{3} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{\mathrm{e}^{-\frac{x^2}{6}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x^2}{6}}}{\left(x^4 + 18x^2 + 27\right)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^4 + 18x^2 + 27\right) + c_2 \left(x^4 + 18x^2 + 27 \left(\int \frac{\mathrm{e}^{-\frac{x^2}{6}}}{\left(x^4 + 18x^2 + 27\right)^2} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Solve

$$5y'' - 2xy' + 10y = 0$$

1.6.1 Solved as second order ode using Kovacic algorithm

Time used: 0.288 (sec)

Writing the ode as

$$5y'' - 2xy' + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 5 \\ B &= -2x \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 55}{25} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 55 \\ t &= 25 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{25} - \frac{11}{5}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 9: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{5} - \frac{11}{2x} - \frac{605}{8x^3} - \frac{33275}{16x^5} - \frac{9150625}{128x^7} - \frac{704598125}{256x^9} - \frac{116258690625}{1024x^{11}} - \frac{10048072546875}{2048x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{5}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{5} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{25}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 55}{25} \\
&= Q + \frac{R}{25} \\
&= \left(\frac{x^2}{25} - \frac{11}{5}\right) + (0) \\
&= \frac{x^2}{25} - \frac{11}{5}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{11}{5}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{11}{5}\right) - (0) \\
&= -\frac{11}{5}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{5} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{11}{5}}{\frac{1}{5}} - 1\right) &&= -6 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{11}{5}}{\frac{1}{5}} - 1\right) &&= 5
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{25} - \frac{11}{5}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{5}$	-6	5

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 5$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^{-} \\ &= 5 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{5}\right) \\ &= -\frac{x}{5} \\ &= -\frac{x}{5} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 5$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^5 + a_4 x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(20x^3 + 12x^2 a_4 + 6x a_3 + 2a_2\right) + 2\left(-\frac{x}{5}\right)\left(5x^4 + 4x^3 a_4 + 3x^2 a_3 + 2x a_2 + a_1\right) + \left(\left(-\frac{1}{5}\right) + \left(-\frac{x}{5}\right)^2 - \left(\frac{x^2}{25}\right.\right.$$

$$\frac{2a_4 x^4}{5} + \frac{4(25 + a_3)\, x^3}{5} + \frac{6(a_2 + 10a_4)\, x^2}{5} + \frac{2(4a_1 + 15a_3)\, x}{5} + 2a_0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = 0, a_1 = \frac{375}{4}, a_2 = 0, a_3 = -25, a_4 = 0\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^5 - 25x^3 + \frac{375}{4}x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= \left(x^5 - 25x^3 + \frac{375}{4}x\right) \mathrm{e}^{\int -\frac{x}{5} dx} \\
&= \left(x^5 - 25x^3 + \frac{375}{4}x\right) \mathrm{e}^{-\frac{x^2}{10}} \\
&= \frac{(4x^5 - 100x^3 + 375x)\, \mathrm{e}^{-\frac{x^2}{10}}}{4}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{5}\, dx} \\
&= z_1 e^{\frac{x^2}{10}} \\
&= z_1 \left(\mathrm{e}^{\frac{x^2}{10}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^5 - 25x^3 + \frac{375}{4}x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{5}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x^2}{5}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{e^{\frac{x^2}{5}}}{\left(x^5 - 25x^3 + \frac{375}{4}x\right)^2} dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^5 - 25x^3 + \frac{375}{4}x \right) + c_2 \left(x^5 - 25x^3 + \frac{375}{4}x \left(\int \frac{e^{\frac{x^2}{5}}}{\left(x^5 - 25x^3 + \frac{375}{4}x\right)^2} dx \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.6.2 Maple step by step solution

Let's solve

$5\frac{d}{dx}y' - 2xy' + 10y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{2xy'}{5} - 2y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{2xy'}{5} + 2y = 0$

- Multiply by denominators

  $5\frac{d}{dx}y' - 2xy' + 10y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  - Convert $x \cdot y'$ to series expansion

$$x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$$

- ◦ Convert $\frac{d}{dx}y'$ to series expansion

$$\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- ◦ Shift index using $k- >k+2$

$$\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite DE with series expansions

$$\sum_{k=0}^{\infty} \left(5a_{k+2}(k+2)\,(k+1) - 2a_k(k-5)\right) x^k = 0$$

- Each term in the series must be 0, giving the recursion relation

$$5(k^2+3k+2)\, a_{k+2} - 2a_k(k-5) = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{2a_k(k-5)}{5(k^2+3k+2)}\right]$$

Solve

$$y'' - x^2 y' - 3xy = 0$$

1.7.1 Solved as second order ode using Kovacic algorithm

Time used: 0.298 (sec)

Writing the ode as

$$y'' - x^2 y' - 3xy = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -x^2 \\ C &= -3x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x(x^3 + 8)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x(x^3 + 8)$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x(x^3 + 8)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 11: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

<u>Attempting to find a solution using case $n = 1$.</u>

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x^2}{2} + \frac{2}{x} - \frac{4}{x^4} + \frac{16}{x^7} - \frac{80}{x^{10}} + \frac{448}{x^{13}} - \frac{2688}{x^{16}} + \frac{16896}{x^{19}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= \frac{x^2}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^4}{4}$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x(x^3+8)}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{1}{4}x^4 + 2x\right) + (0) \\ &= \frac{1}{4}x^4 + 2x \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is 2. Now b can be found.

$$\begin{aligned} b &= (2) - (0) \\ &= 2 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x^2}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{2}{\frac{1}{2}} - 2\right) &= 1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{2}{\frac{1}{2}} - 2\right) &= -3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x(x^3+8)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$\frac{x^2}{2}$	1	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x^2}{2}\right) \\ &= \frac{x^2}{2} \\ &= \frac{x^2}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{x^2}{2}\right)(1) + \left((x) + \left(\frac{x^2}{2}\right)^2 - \left(\frac{x(x^3+8)}{4}\right)\right) = 0$$

$$-xa_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x)\, e^{\int \frac{x^2}{2} dx} \\ &= (x)\, e^{\frac{x^3}{6}} \\ &= x\, e^{\frac{x^3}{6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2}{1} \, dx} \\ &= z_1 e^{\frac{x^3}{6}} \\ &= z_1 \left(e^{\frac{x^3}{6}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{\frac{x^3}{3}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\frac{x^3}{3}}}{(y_1)^2} \, dx \\ &= y_1 \left(\int \frac{e^{-\frac{x^3}{3}}}{x^2} dx \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{x^3}{3}} x\right) + c_2 \left(\mathrm{e}^{\frac{x^3}{3}} x \left(\int \frac{\mathrm{e}^{-\frac{x^3}{3}}}{x^2} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.7.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' - x^2 y' - 3xy = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x \cdot y$ to series expansion

  $x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+1}$

- ○ Shift index using $k- >k-1$

  $x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^k$

- ○ Convert $x^2 \cdot y'$ to series expansion

  $x^2 \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^{k+1}$

- ○ Shift index using $k- >k-1$

  $x^2 \cdot y' = \sum_{k=1}^{\infty} a_{k-1}(k-1)\, x^k$

- ○ Convert $\frac{d}{dx}y'$ to series expansion

  $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ○ Shift index using $k- >k+2$

$\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\,x^{k}$

Rewrite ODE with series expansions

$2a_{2}+\left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)(k+1)-a_{k-1}(k+2)\right) x^{k}\right) = 0$

- Each term must be 0

  $2a_{2} = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\left(k a_{k+2}-a_{k-1}+a_{k+2}\right) = 0$

- Shift index using $k->k+1$

  $(k+3)\left((k+1)\,a_{k+3}-a_{k}+a_{k+3}\right) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_{k} x^{k}, a_{k+3} = \frac{a_{k}}{k+2}, 2a_{2} = 0\right]$

Problem number : 8
Date solved : `Monday, October 21, 2024 at 04:54:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''+2 x y'-2 y=0$$

1.8.1 Solved as second order ode using Kovacic algorithm

Time used: 0.300 (sec)

Writing the ode as

$$\left(x^2+1\right) y''+2 x y'-2 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= 2x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2x^2 + 3}{(x^2 + 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2x^2 + 3$$
$$t = (x^2 + 1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2x^2 + 3}{(x^2 + 1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 13: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-i)^2} - \frac{1}{4(x+i)^2} - \frac{5i}{4(x-i)} + \frac{5i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^2+3}{(x^2+1)^2}$$

Since the gcd$(s,t)=1$. This gives $b=2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2x^2+3}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
i	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-i$	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=2$ then

$$\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{-}\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x - 2i} + \frac{1}{2x + 2i} + (0) \\
&= \frac{1}{2x - 2i} + \frac{1}{2x + 2i} \\
&= \frac{x}{x^2 + 1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x - 2i} + \frac{1}{2x + 2i}\right)(1) + \left(\left(-\frac{1}{2(x - i)^2} - \frac{1}{2(x + i)^2}\right) + \left(\frac{1}{2x - 2i} + \frac{1}{2x + 2i}\right)^2 - \left(\frac{2x^2 + 3}{(x^2 + 1)^2} \right.\right.
$$
$$
- \frac{2(x^2 + 1)\, a_0}{(-x + i)^2 (x + i)^2}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, e^{\int \left(\frac{1}{2x - 2i} + \frac{1}{2x + 2i}\right) dx} \\
&= (x) \sqrt{(-x + i)(x + i)} \\
&= x\sqrt{-x^2 - 1}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2+1}\,dx} \\
&= z_1 e^{-\frac{\ln\left(x^2+1\right)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x^2+1}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = ix$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x^2+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(\arctan(x) + \frac{1}{x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(ix) + c_2\left(ix\left(\arctan(x) + \frac{1}{x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.9 problem 9

Internal problem ID [8147]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 9
Date solved : `Monday, October 21, 2024 at 04:54:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' - 2y = 0$$

1.9.1 Solved as second order ode using Kovacic algorithm

Time used: 0.225 (sec)

Writing the ode as

$$y'' + xy' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 10}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 + 10$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} + \frac{5}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 14: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

<u>Attempting to find a solution using case $n = 1$.</u>

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} + \frac{5}{2x} - \frac{25}{4x^3} + \frac{125}{4x^5} - \frac{3125}{16x^7} + \frac{21875}{16x^9} - \frac{328125}{32x^{11}} + \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 + 10}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{x^2}{4} + \frac{5}{2}\right) + (0) \\
&= \frac{x^2}{4} + \frac{5}{2}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{5}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{5}{2}\right) - (0) \\
&= \frac{5}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{5}{2}}{\frac{1}{2}} - 1\right) &= 2 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{5}{2}}{\frac{1}{2}} - 1\right) &= -3
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} + \frac{5}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	2	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = 2$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^{+} \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x}{2}\right) \\ &= \frac{x}{2} \\ &= \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{x}{2}\right)(2x + a_1) + \left(\left(\frac{1}{2}\right) + \left(\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} + \frac{5}{2}\right)\right) = 0$$

$$-a_1 x - 2a_0 + 2 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x^2+1)\, \mathrm{e}^{\int \frac{x}{2} dx} \\ &= (x^2+1)\, \mathrm{e}^{\frac{x^2}{4}} \\ &= (x^2+1)\, \mathrm{e}^{\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1} \, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 + 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x^2}{2}}}{(x^2+1)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1(x^2+1) + c_2\left(x^2+1\left(\int \frac{e^{-\frac{x^2}{2}}}{(x^2+1)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.9.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + xy' - 2y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

- □ Rewrite DE with series expansions
  - ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$
  - ◦ Convert $\frac{d}{dx}y'$ to series expansion

    $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
  - ◦ Shift index using $k- >k+2$

    $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} (a_{k+2}(k+2)(k+1) + a_k(k-2))\, x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k^2+3k+2)\, a_{k+2} + a_k(k-2) = 0$

- Recursion relation; series terminates at $k=2$

  $a_{k+2} = -\frac{a_k(k-2)}{k^2+3k+2}$

- Apply recursion relation for $k=0$

$a_2 = a_0$

- Terminating series solution of the ODE. Use reduction of order to find the second linearly ind

  $y = A_2x^2 + A_1x + a_0$

1.10 problem 10

Internal problem ID [8148]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 10
Date solved : `Monday, October 21, 2024 at 04:54:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2-6x+10\right)y''-4(x-3)\,y'+6y=0$$

1.10.1 Solved as second order ode using Kovacic algorithm

Time used: 0.306 (sec)

Writing the ode as

$$\left(x^2-6x+10\right)y''+(-4x+12)\,y'+6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2-6x+10\\B&=-4x+12\\C&=6\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-8}{(x^2 - 6x + 10)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -8$$
$$t = (x^2 - 6x + 10)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{8}{(x^2 - 6x + 10)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 16: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 6x + 10)^2$. There is a pole at $x = 3 + i$ of order 2. There is a pole at $x = 3 - i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{(x - 3 - i)^2} + \frac{2}{(x - 3 + i)^2} + \frac{2i}{x - 3 - i} - \frac{2i}{x - 3 + i}$$

For the pole at $x = 3 + i$ let b be the coefficient of $\frac{1}{(x-3-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

For the pole at $x = 3 - i$ let b be the coefficient of $\frac{1}{(x-3+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{8}{(x^2 - 6x + 10)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$3 + i$	2	0	2	-1
$3 - i$	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x - 3 - i} + \frac{2}{x - 3 + i} + (-)(0) \\ &= -\frac{1}{x - 3 - i} + \frac{2}{x - 3 + i} \\ &= \frac{x - 3 - 3i}{x^2 - 6x + 10} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x-3-i} + \frac{2}{x-3+i}\right)(0) + \left(\left(\frac{1}{(x-3-i)^2} - \frac{2}{(x-3+i)^2}\right) + \left(-\frac{1}{x-3-i} + \frac{2}{x-3+i}\right)^2\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{x-3-i} + \frac{2}{x-3+i}\right) dx} \\ &= \frac{(x^2 - 6x + 10)^2}{(ix - 3i + 1)^3} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x+12}{x^2-6x+10} \, dx} \\ &= z_1 e^{\ln(x^2-6x+10)} \\ &= z_1 \left(x^2 - 6x + 10\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2 - 6x + 10)^3}{(ix - 3i + 1)^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{-4x+12}{x^2-6x+10}\,dx}}{(y_1)^2}\,dx$$
$$= y_1 \int \frac{e^{2\ln(x^2-6x+10)}}{(y_1)^2}\,dx$$
$$= y_1 \left(\frac{x^2-6x+\frac{26}{3}}{(x-3+i)^3}\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{(x^2-6x+10)^3}{(ix-3i+1)^3}\right) + c_2 \left(\frac{(x^2-6x+10)^3}{(ix-3i+1)^3} \left(\frac{x^2-6x+\frac{26}{3}}{(x-3+i)^3}\right)\right)$$

Will add steps showing solving for IC soon.

Solve

$$\left(x^2+6x\right)y''+(3x+9)\,y'-3y=0$$

1.11.1 Solved as second order ode using Kovacic algorithm

Time used: 0.233 (sec)

Writing the ode as

$$\left(x^2+6x\right)y''+(3x+9)\,y'-3y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+6x \\ B &= 3x+9 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{15x^2 + 90x - 27}{4\left(x^2 + 6x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 15x^2 + 90x - 27$$
$$t = 4\left(x^2 + 6x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15x^2 + 90x - 27}{4\left(x^2 + 6x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 17: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + 6x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -6$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} - \frac{3}{16(x+6)^2} + \frac{11}{16x} - \frac{11}{16(x+6)}$$

For the pole at $x = -6$ let b be the coefficient of $\frac{1}{(x+6)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15x^2 + 90x - 27}{4(x^2+6x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{15}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{5}{2}\\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{3}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{15x^2+90x-27}{4\left(x^2+6x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-6	2	0	$\frac{3}{4}$	$\frac{1}{4}$
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=\frac{5}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+-\left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right)\\
&= \frac{5}{2}-\left(\frac{3}{2}\right)\\
&= 1
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{3}{4\left(x+6\right)} + \frac{3}{4x} + (0) \\
&= \frac{3}{4\left(x+6\right)} + \frac{3}{4x} \\
&= \frac{\frac{3x}{2} + \frac{9}{2}}{x\left(x+6\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{3}{4\left(x+6\right)} + \frac{3}{4x}\right)(1) + \left(\left(-\frac{3}{4\left(x+6\right)^2} - \frac{3}{4x^2}\right) + \left(\frac{3}{4\left(x+6\right)} + \frac{3}{4x}\right)^2 - \left(\frac{15x^2 + 90x - 27}{4\left(x^2+6x\right)^2}\right)\right) = \frac{9 - 3a_0}{x\left(x+6\right)} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 3\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + 3
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x+3\right) \mathrm{e}^{\int \left(\frac{3}{4(x+6)} + \frac{3}{4x}\right) dx} \\
&= \left(x+3\right) \left(x(x+6)\right)^{3/4} \\
&= \left(x+3\right) \left(x(x+6)\right)^{3/4}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x+9}{x^2+6x}\,dx} \\
&= z_1 e^{-\frac{3\ln(x(x+6))}{4}} \\
&= z_1 \left(\frac{1}{\left(x\left(x+6\right)\right)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x+3
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x+9}{x^2+6x}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln(x(x+6))}{2}}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(-\frac{\left(x+6\right)x(2x^2+12x+9)}{81\left(x+3\right)\left(x\left(x+6\right)\right)^{3/2}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x+3) + c_2\left(x+3\left(-\frac{\left(x+6\right)x(2x^2+12x+9)}{81\left(x+3\right)\left(x\left(x+6\right)\right)^{3/2}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.11.2 Maple step by step solution

Let's solve

$(x^2+6x)\left(\frac{d}{dx}y'\right)+(3x+9)\,y'-3y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=\frac{3y}{x(x+6)}-\frac{3(x+3)y'}{x(x+6)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{3(x+3)y'}{x(x+6)}-\frac{3y}{x(x+6)}=0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{3(x+3)}{x(x+6)},P_3(x)=-\frac{3}{x(x+6)}\right]$

  ◦ $(x+6)\cdot P_2(x)$ is analytic at $x=-6$

  $\left((x+6)\cdot P_2(x)\right)\Big|_{x=-6}=\frac{3}{2}$

  ◦ $(x+6)^2\cdot P_3(x)$ is analytic at $x=-6$

  $\left((x+6)^2\cdot P_3(x)\right)\Big|_{x=-6}=0$

  ◦ $x=-6$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-6$

- Multiply by denominators

$x(x+6)\left(\frac{d}{dx}y'\right)+(3x+9)\,y'-3y=0$

- Change variables using $x=u-6$ so that the regular singular point is at $u=0$

$(u^2-6u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(3u-9)\left(\frac{d}{du}y(u)\right)-3y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-3a_0r(1+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} (-3a_{k+1}(k+1+r)\,(2k+3+2r) + a_k(k+r+3)\,(k+r-1))\, u^{k+r}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-3r(1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-6(k+1+r)\left(k+\frac{3}{2}+r\right) a_{k+1} + a_k(k+r+3)\,(k+r-1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k(k+r+3)(k+r-1)}{3(k+1+r)(2k+3+2r)}$$

- Recursion relation for $r = 0$; series terminates at $k = 1$

$$a_{k+1} = \frac{a_k(k+3)(k-1)}{3(k+1)(2k+3)}$$

- Apply recursion relation for $k = 0$

$$a_1 = -\frac{a_0}{3}$$

- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

$$y(u) = a_0 \cdot \left(1 - \frac{u}{3}\right)$$

- Revert the change of variables $u = x + 6$

$$\left[y = a_0\left(-1 - \frac{x}{3}\right)\right]$$

- Recursion relation for $r = -\frac{1}{2}$

$$a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}$$

- Solution for $r = -\frac{1}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}\right]$$

- Revert the change of variables $u = x + 6$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+6)^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k \left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y = a_0\left(-1-\frac{x}{3}\right) + \left(\sum_{k=0}^{\infty} b_k (x+6)^{k-\frac{1}{2}}\right), b_{k+1} = \frac{b_k \left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}\right]$$

1.12 problem 12

Internal problem ID [8150]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 12
Date solved : `Monday, October 21, 2024 at 04:54:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$ty'' + \left(t^2 - 1\right) y' + t^2 y = 0$$

1.12.1 Solved as second order ode using Kovacic algorithm

Time used: 0.322 (sec)

Writing the ode as

$$ty'' + \left(t^2 - 1\right) y' + t^2 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= t^2 - 1 \\ C &= t^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{t^4 - 4t^3 + 3}{4t^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= t^4 - 4t^3 + 3 \\
t &= 4t^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(t) = \left(\frac{t^4 - 4t^3 + 3}{4t^2}\right) z(t) \tag{7}
$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$
y = z(t)\, e^{-\int \frac{B}{2A}\, dt}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 19: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{t^2}{4} - t + \frac{3}{4t^2}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{1} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{t}{2} - 1 - \frac{1}{t} - \frac{2}{t^2} - \frac{17}{4t^3} - \frac{25}{2t^4} - \frac{75}{2t^5} - \frac{117}{t^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i t^i \\ &= -1 + \frac{t}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1 - t + \frac{1}{4}t^2$$

This shows that the coefficient of 1 in the above is 1. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^4 - 4t^3 + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}t^2 - t\right) + \left(\frac{3}{4t^2}\right) \\ &= \frac{t^2}{4} - t + \frac{3}{4t^2} \end{aligned}$$

We see that the coefficient of the term t in the quotient is 0. Now b can be found.

$$\begin{aligned} b &= (0) - (1) \\ &= -1 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= -1 + \frac{t}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 1\right) &= -\frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 1\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{t^4 - 4t^3 + 3}{4t^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$-1 + \frac{t}{2}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{t-c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2t} + (-)\left(-1+\frac{t}{2}\right) \\
&= -\frac{1}{2t} + 1 - \frac{t}{2} \\
&= -\frac{(t-1)^2}{2t}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d=1$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(t) = t + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{2t} + 1 - \frac{t}{2}\right)(1) + \left(\left(\frac{1}{2t^2} - \frac{1}{2}\right) + \left(-\frac{1}{2t} + 1 - \frac{t}{2}\right)^2 - \left(\frac{t^4 - 4t^3 + 3}{4t^2}\right)\right) = 0
$$

$$
\frac{(a_0+1)(t-1)}{t} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = -1\}
$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$
p(t) = t - 1
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= (t-1)\,\mathrm{e}^{\int \left(-\frac{1}{2t} + 1 - \frac{t}{2}\right) dt} \\
&= (t-1)\,\mathrm{e}^{-\frac{t^2}{4} + t - \frac{\ln(t)}{2}} \\
&= \frac{(t-1)\,\mathrm{e}^{-\frac{t(t-4)}{4}}}{\sqrt{t}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{t^2-1}{t}\,dt} \\
&= z_1 e^{-\frac{t^2}{4}+\frac{\ln(t)}{2}} \\
&= z_1\left(\sqrt{t}\,\mathrm{e}^{-\frac{t^2}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (t-1)\,\mathrm{e}^{-\frac{t(t-2)}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{t^2-1}{t}\,dt}}{(y_1)^2}\,dt \\
&= y_1 \int \frac{e^{-\frac{t^2}{2}+\ln(t)}}{(y_1)^2}\,dt \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{t^2}{2}+\ln(t)}\mathrm{e}^{t(t-2)}}{(t-1)^2}dt\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left((t-1)\,\mathrm{e}^{-\frac{t(t-2)}{2}}\right) + c_2\left((t-1)\,\mathrm{e}^{-\frac{t(t-2)}{2}}\left(\int \frac{\mathrm{e}^{-\frac{t^2}{2}+\ln(t)}\mathrm{e}^{t(t-2)}}{(t-1)^2}dt\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.12.2 Maple step by step solution

Let's solve

$t\left(\frac{d}{dt}y'\right)+\left(t^{2}-1\right)y'+t^{2}y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dt}y'$

- Isolate 2nd derivative

$\frac{d}{dt}y'=-yt-\frac{\left(t^{2}-1\right)y'}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dt}y'+\frac{\left(t^{2}-1\right)y'}{t}+yt=0$

□ Check to see if $t_0=0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(t)=\frac{t^{2}-1}{t}, P_3(t)=t\right]$

- ◦ $t\cdot P_2(t)$ is analytic at $t=0$

  $\left(t\cdot P_2(t)\right)\Big|_{t=0}=-1$

- ◦ $t^{2}\cdot P_3(t)$ is analytic at $t=0$

  $\left(t^{2}\cdot P_3(t)\right)\Big|_{t=0}=0$

- ◦ $t=0$is a regular singular point

  Check to see if $t_0=0$ is a regular singular point

  $t_0=0$

- Multiply by denominators

$t\left(\frac{d}{dt}y'\right)+\left(t^{2}-1\right)y'+t^{2}y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_k t^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $t^{2}\cdot y$ to series expansion

  $t^{2}\cdot y=\sum_{k=0}^{\infty}a_k t^{k+r+2}$

- ◦ Shift index using $k->k-2$

  $t^{2}\cdot y=\sum_{k=2}^{\infty}a_{k-2} t^{k+r}$

- ◦ Convert $t^{m}\cdot y'$ to series expansion for $m=0..2$

$$t^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, t^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$t^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$$

- Convert $t \cdot \left(\frac{d}{dt}y'\right)$ to series expansion

  $$t \cdot \left(\frac{d}{dt}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, t^{k+r-1}$$

- Shift index using $k- >k+1$

  $$t \cdot \left(\frac{d}{dt}y'\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, t^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-2+r)\, t^{-1+r} + a_1(1+r)\,(-1+r)\, t^r + (a_2(2+r)\, r + a_0 r)\, t^{1+r} + \left(\sum_{k=2}^{\infty} (a_{k+1}(k+1+r)\,(k+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- The coefficients of each power of t must be 0

  $[a_1(1+r)\,(-1+r) = 0, a_2(2+r)\, r + a_0 r = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_1 = 0, a_2 = -\frac{a_0}{2+r}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)\,(k+r-1) + a_{k-1}(k+r-1) + a_{k-2} = 0$

- Shift index using $k- >k+2$

  $a_{k+3}(k+3+r)\,(k+1+r) + a_{k+1}(k+1+r) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+3} = -\frac{k a_{k+1} + r a_{k+1} + a_k + a_{k+1}}{(k+3+r)(k+1+r)}$

- Recursion relation for $r = 0$

  $a_{k+3} = -\frac{k a_{k+1} + a_k + a_{k+1}}{(k+3)(k+1)}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k t^k, a_{k+3} = -\frac{k a_{k+1} + a_k + a_{k+1}}{(k+3)(k+1)}, a_1 = 0, a_2 = -\frac{a_0}{2}\right]$

- Recursion relation for $r = 2$

  $a_{k+3} = -\frac{k a_{k+1} + a_k + 3 a_{k+1}}{(k+5)(k+3)}$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+3} = -\frac{k a_{k+1} + a_k + 3 a_{k+1}}{(k+5)(k+3)}, a_1 = 0, a_2 = -\frac{a_0}{4}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k t^k\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+3} = -\frac{k a_{k+1} + a_k + a_{k+1}}{(k+3)(k+1)}, a_1 = 0, a_2 = -\frac{a_0}{2}, b_{k+3} = -\frac{k b_{k+1} + b_k + 3 b_k}{(k+5)(k+3)}$$

Solve

$$t^2 y'' - t(t+2)\, y' + (t+2)\, y = 0$$

1.13.1 Solved as second order ode using Kovacic algorithm

Time used: 0.102 (sec)

Writing the ode as

$$t^2 y'' + \left(-t^2 - 2t\right) y' + (t+2)\, y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^2 \\ B &= -t^2 - 2t \\ C &= t + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = y e^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = r z(t) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(t) = \frac{z(t)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 21: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(t) = \mathrm{e}^{-\frac{t}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-t^2-2t}{t^2}\,dt} \\
&= z_1 e^{\frac{t}{2}+\ln(t)} \\
&= z_1 \left(t\,\mathrm{e}^{\frac{t}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = t
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-t^2-2t}{t^2}\,dt}}{(y_1)^2}\,dt \\
&= y_1 \int \frac{e^{t+2\ln(t)}}{(y_1)^2}\,dt \\
&= y_1 \left(\frac{\mathrm{e}^{t+2\ln(t)}}{t^2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(t) + c_2 \left(t \left(\frac{e^{t+2\ln(t)}}{t^2} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.13.2 Maple step by step solution

Let's solve
$t^2\left(\frac{d}{dt}y'\right) - t(t+2)\,y' + (t+2)\,y = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d}{dt}y'$
- Isolate 2nd derivative
  $\frac{d}{dt}y' = -\frac{(t+2)y}{t^2} + \frac{(t+2)y'}{t}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d}{dt}y' - \frac{(t+2)y'}{t} + \frac{(t+2)y}{t^2} = 0$

☐ Check to see if $t_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(t) = -\frac{t+2}{t}, P_3(t) = \frac{t+2}{t^2}\right]$
  - $t \cdot P_2(t)$ is analytic at $t = 0$
    $\left.(t \cdot P_2(t))\right|_{t=0} = -2$
  - $t^2 \cdot P_3(t)$ is analytic at $t = 0$
    $\left.(t^2 \cdot P_3(t))\right|_{t=0} = 2$
  - $t = 0$is a regular singular point
    Check to see if $t_0 = 0$ is a regular singular point
    $t_0 = 0$

- Multiply by denominators
  $t^2\left(\frac{d}{dt}y'\right) - t(t+2)\,y' + (t+2)\,y = 0$
- Assume series solution for y
  $y = \sum_{k=0}^{\infty} a_k t^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $t^m \cdot y$ to series expansion for $m = 0..1$

  $t^m \cdot y = \sum_{k=0}^{\infty} a_k t^{k+r+m}$

- Shift index using $k- >k - m$

  $t^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} t^{k+r}$

- Convert $t^m \cdot y'$ to series expansion for $m = 1..2$

  $t^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, t^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $t^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$

- Convert $t^2 \cdot \left(\frac{d}{dt}y'\right)$ to series expansion

  $t^2 \cdot \left(\frac{d}{dt}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)\,(-2+r)\, t^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-1)\,(k+r-2) - a_{k-1}(k+r-2)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)\,(a_k(k+r-1) - a_{k-1}) = 0$

- Shift index using $k- >k + 1$

  $(k+r-1)\,(a_{k+1}(k+r) - a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+r}$

- Recursion relation for $r = 1$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k t^{k+1}, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+2}$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+1} = \frac{a_k}{k+2}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k t^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+2}\right]$$

1.14 problem 14

Internal problem ID [8152]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 14
Date solved : `Monday, October 21, 2024 at 04:54:32 PM`
CAS classification : `[_Laguerre]`

Solve

$$ty'' - (1+t)\,y' + y = 0$$

1.14.1 Solved as second order ode using Kovacic algorithm

Time used: 0.240 (sec)

Writing the ode as

$$ty'' + (-1-t)\,y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= -1-t \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 2t + 3}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = t^2 - 2t + 3$$
$$t = 4t^2$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 2t + 3}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 23: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2t} + \frac{3}{4t^2}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{2t^2} + \frac{1}{2t^3} + \frac{1}{4t^4} - \frac{1}{4t^5} - \frac{3}{4t^6} - \frac{3}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 2t + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 3}{4t^2}\right) \\ &= \frac{1}{4} + \frac{-2t + 3}{4t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 2t + 3}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2t} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} - \frac{1}{2t} \\ &= \frac{t-1}{2t}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(\frac{1}{2} - \frac{1}{2t}\right)(0) + \left(\left(\frac{1}{2t^2}\right) + \left(\frac{1}{2} - \frac{1}{2t}\right)^2 - \left(\frac{t^2-2t+3}{4t^2}\right) \right) &= 0 \\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(t) &= p e^{\int \omega \, dt} \\ &= \mathrm{e}^{\int \left(\frac{1}{2} - \frac{1}{2t}\right) dt} \\ &= \frac{\mathrm{e}^{\frac{t}{2}}}{\sqrt{t}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1-t}{t}\, dt} \\ &= z_1 e^{\frac{t}{2} + \frac{\ln(t)}{2}} \\ &= z_1 \left(\sqrt{t}\, \mathrm{e}^{\frac{t}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1-t}{t}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{t+\ln(t)}}{(y_1)^2}\, dt \\ &= y_1 \left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^t\right) + c_2 \left(\mathrm{e}^t \left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.14.2 Maple step by step solution

Let's solve

$t\left(\frac{d}{dt}y'\right) - (1+t)\,y' + y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dt}y'$

- Isolate 2nd derivative

  $\frac{d}{dt}y' = -\frac{y}{t} + \frac{(1+t)y'}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dt}y' - \frac{(1+t)y'}{t} + \frac{y}{t} = 0$

□ Check to see if $t_0 = 0$ is a regular singular point

- Define functions
  $\left[P_2(t) = -\frac{1+t}{t}, P_3(t) = \frac{1}{t}\right]$
- $t \cdot P_2(t)$ is analytic at $t = 0$
  $(t \cdot P_2(t))\bigg|_{t=0} = -1$
- $t^2 \cdot P_3(t)$ is analytic at $t = 0$
  $(t^2 \cdot P_3(t))\bigg|_{t=0} = 0$
- $t = 0$is a regular singular point
  Check to see if $t_0 = 0$ is a regular singular point
  $t_0 = 0$

- Multiply by denominators
  $t\left(\frac{d}{dt}y'\right) + (-1 - t)\, y' + y = 0$
- Assume series solution for y
  $y = \sum_{k=0}^{\infty} a_k t^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $t^m \cdot y'$ to series expansion for $m = 0..1$
  $t^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, t^{k+r-1+m}$
- Shift index using $k- >k + 1 - m$
  $t^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k + 1 - m + r)\, t^{k+r}$
- Convert $t \cdot \left(\frac{d}{dt}y'\right)$ to series expansion
  $t \cdot \left(\frac{d}{dt}y'\right) = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, t^{k+r-1}$
- Shift index using $k- >k + 1$
  $t \cdot \left(\frac{d}{dt}y'\right) = \sum_{k=-1}^{\infty} a_{k+1} (k + 1 + r)\,(k + r)\, t^{k+r}$

  Rewrite ODE with series expansions
  $a_0 r(-2 + r)\, t^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k + 1 + r)\,(k + r - 1) - a_k(k + r - 1)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-2 + r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_{k+1}(k+1+r)-a_k\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k}{k+1+r}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{a_k}{k+1}$
- Solution for $r=0$
  $\left[y=\sum_{k=0}^{\infty} a_k t^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Recursion relation for $r=2$
  $a_{k+1}=\frac{a_k}{k+3}$
- Solution for $r=2$
  $\left[y=\sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y=\left(\sum_{k=0}^{\infty} a_k t^k\right)+\left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$

1.15 problem 15

Internal problem ID [8153]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 15
Date solved : `Monday, October 21, 2024 at 04:54:33 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-t)\,y''+ty'-y=0$$

1.15.1 Solved as second order ode using Kovacic algorithm

Time used: 0.256 (sec)

Writing the ode as

$$(1-t)\,y''+ty'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=1-t\\B&=t\\C&=-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t)=rz(t) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 4t + 6}{4(-1+t)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = t^2 - 4t + 6$$
$$t = 4(-1+t)^2$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 4t + 6}{4(-1+t)^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 25: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1+t)^2$. There is a pole at $t = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2(-1+t)} + \frac{3}{4(-1+t)^2}$$

For the pole at $t = 1$ let b be the coefficient of $\frac{1}{(-1+t)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{t^3} + \frac{11}{4t^4} + \frac{21}{4t^5} + \frac{15}{2t^6} + \frac{6}{t^7} - \frac{117}{16t^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 4t + 6}{4t^2 - 8t + 4} \\ &= Q + \frac{R}{4t^2 - 8t + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 5}{4t^2 - 8t + 4}\right) \\ &= \frac{1}{4} + \frac{-2t + 5}{4t^2 - 8t + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 4t + 6}{4(-1+t)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(-1+t)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(-1+t)} + \frac{1}{2} \\
&= \frac{t-2}{2t-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(-1+t)^2} \right) + \left(-\frac{1}{2(-1+t)} + \frac{1}{2} \right)^2 - \left(\frac{t^2-4t+6}{4(-1+t)^2} \right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= e^{\int \left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right) dt} \\
&= \frac{e^{\frac{t}{2}}}{\sqrt{-1+t}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dt} \\
&= z_1 e^{-\int \frac{1}{2} \frac{t}{1-t} \, dt} \\
&= z_1 e^{\frac{t}{2} + \frac{\ln(-1+t)}{2}} \\
&= z_1 \left(\sqrt{-1+t}\, e^{\frac{t}{2}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{t}{1-t}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{t+\ln(-1+t)}}{(y_1)^2}\, dt \\ &= y_1 \left(-\frac{t\, \mathrm{e}^{t+\ln(-1+t)} \mathrm{e}^{-2t}}{-1+t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^t\right) + c_2 \left(\mathrm{e}^t \left(-\frac{t\, \mathrm{e}^{t+\ln(-1+t)} \mathrm{e}^{-2t}}{-1+t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.15.2 Maple step by step solution

Let's solve

$(1-t)\left(\frac{d}{dt}y'\right) + ty' - y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dt}y'$

- Isolate 2nd derivative

  $\frac{d}{dt}y' = -\frac{y}{-1+t} + \frac{ty'}{-1+t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dt}y' - \frac{ty'}{-1+t} + \frac{y}{-1+t} = 0$

□ Check to see if $t_0 = 1$ is a regular singular point

- Define functions
  $\left[P_2(t)=-\frac{t}{-1+t}, P_3(t)=\frac{1}{-1+t}\right]$
- $(-1+t)\cdot P_2(t)$ is analytic at $t=1$
  $$\left((-1+t)\cdot P_2(t)\right)\Big|_{t=1}=-1$$
- $(-1+t)^2\cdot P_3(t)$ is analytic at $t=1$
  $$\left((-1+t)^2\cdot P_3(t)\right)\Big|_{t=1}=0$$
- $t=1$is a regular singular point
  Check to see if $t_0=1$ is a regular singular point
  $t_0=1$

- Multiply by denominators
  $(-1+t)\left(\frac{d}{dt}y'\right)-ty'+y=0$
- Change variables using $t=u+1$ so that the regular singular point is at $u=0$
  $u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$
- Assume series solution for $y(u)$
  $$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$$

☐ Rewrite ODE with series expansions
- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$$
- Shift index using $k->k+1-m$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$$
- Convert $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-1}$$
- Shift index using $k->k+1$
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)\,u^{k+r}$$
  Rewrite ODE with series expansions
  $$a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r)=0$

- Values of r that satisfy the indicial equation
  $r \in \{0,2\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_{k+1}(k+1+r)-a_k\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k}{k+1+r}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{a_k}{k+1}$
- Solution for $r=0$
  $$\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+1}=\frac{a_k}{k+1}\right]$$
- Revert the change of variables $u=-1+t$
  $$\left[y=\sum_{k=0}^{\infty} a_k(-1+t)^k, a_{k+1}=\frac{a_k}{k+1}\right]$$
- Recursion relation for $r=2$
  $a_{k+1}=\frac{a_k}{k+3}$
- Solution for $r=2$
  $$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$$
- Revert the change of variables $u=-1+t$
  $$\left[y=\sum_{k=0}^{\infty} a_k(-1+t)^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$$
- Combine solutions and rename parameters
  $$\left[y=\left(\sum_{k=0}^{\infty} a_k(-1+t)^k\right)+\left(\sum_{k=0}^{\infty} b_k(-1+t)^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$$

1.16 problem 16

Internal problem ID [8154]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 16
Date solved : `Monday, October 21, 2024 at 04:54:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right)y = 0$$

1.16.1 Solved as second order ode using Kovacic algorithm

Time used: 0.167 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= x^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 27: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(x)}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\cos (x)}{\sqrt{x}}\right) + c_2 \left(\frac{\cos (x)}{\sqrt{x}} (\tan (x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.16.2 Maple step by step solution

Let's solve

$x^2 \left(\frac{d}{dx} y'\right) + x y' + \left(x^2 - \frac{1}{4}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$

- Isolate 2nd derivative

  $\frac{d}{dx} y' = -\frac{(4x^2-1)y}{4x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

1.17 problem 17

Internal problem ID [8155]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 17
Date solved : `Monday, October 21, 2024 at 04:54:35 PM`
CAS classification : `[_Laguerre]`

Solve

$$ty'' - (1+t)\,y' + y = 0$$

1.17.1 Solved as second order ode using Kovacic algorithm

Time used: 0.277 (sec)

Writing the ode as

$$ty'' + (-1-t)\,y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= -1-t \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 2t + 3}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = t^2 - 2t + 3$$
$$t = 4t^2$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 2t + 3}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 29: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4t^2} - \frac{1}{2t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{2t^2} + \frac{1}{2t^3} + \frac{1}{4t^4} - \frac{1}{4t^5} - \frac{3}{4t^6} - \frac{3}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 2t + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 3}{4t^2}\right) \\ &= \frac{1}{4} + \frac{-2t + 3}{4t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{1}{2}\right) - (0) \\
&= -\frac{1}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{t^2 - 2t + 3}{4t^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2t} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} - \frac{1}{2t} \\
&= \frac{t-1}{2t}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2} - \frac{1}{2t}\right)(0) + \left(\left(\frac{1}{2t^2}\right) + \left(\frac{1}{2} - \frac{1}{2t}\right)^2 - \left(\frac{t^2 - 2t + 3}{4t^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= \mathrm{e}^{\int \left(\frac{1}{2} - \frac{1}{2t}\right) dt} \\
&= \frac{\mathrm{e}^{\frac{t}{2}}}{\sqrt{t}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dt} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-1-t}{t} \, dt} \\
&= z_1 e^{\frac{t}{2} + \frac{\ln(t)}{2}} \\
&= z_1 \left(\sqrt{t}\, \mathrm{e}^{\frac{t}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1-t}{t}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{t+\ln(t)}}{(y_1)^2}\, dt \\ &= y_1 \left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^t\right) + c_2 \left(\mathrm{e}^t \left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.17.2 Maple step by step solution

Let's solve

$t\left(\frac{d}{dt}y'\right) - (1+t)\,y' + y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dt}y'$

- Isolate 2nd derivative

  $\frac{d}{dt}y' = -\frac{y}{t} + \frac{(1+t)y'}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dt}y' - \frac{(1+t)y'}{t} + \frac{y}{t} = 0$

☐ Check to see if $t_0 = 0$ is a regular singular point

- Define functions
  $\left[P_2(t) = -\frac{1+t}{t}, P_3(t) = \frac{1}{t}\right]$
- $t \cdot P_2(t)$ is analytic at $t = 0$
  $$\left(t \cdot P_2(t)\right)\Big|_{t=0} = -1$$
- $t^2 \cdot P_3(t)$ is analytic at $t = 0$
  $$\left(t^2 \cdot P_3(t)\right)\Big|_{t=0} = 0$$
- $t = 0$is a regular singular point
  Check to see if $t_0 = 0$ is a regular singular point
  $t_0 = 0$

- Multiply by denominators
  $t\left(\frac{d}{dt}y'\right) + (-1-t)\, y' + y = 0$
- Assume series solution for y
  $$y = \sum_{k=0}^{\infty} a_k t^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $t^m \cdot y'$ to series expansion for $m = 0..1$
  $$t^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, t^{k+r-1+m}$$
- Shift index using $k- >k + 1 - m$
  $$t^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$$
- Convert $t \cdot \left(\frac{d}{dt}y'\right)$ to series expansion
  $$t \cdot \left(\frac{d}{dt}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, t^{k+r-1}$$
- Shift index using $k- >k + 1$
  $$t \cdot \left(\frac{d}{dt}y'\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, t^{k+r}$$
  Rewrite ODE with series expansions
  $$a_0 r(-2+r)\, t^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+r-1) - a_k(k+r-1)\right) t^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_{k+1}(k+1+r)-a_k\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k}{k+1+r}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{a_k}{k+1}$
- Solution for $r=0$
  $\left[y=\sum_{k=0}^{\infty} a_k t^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Recursion relation for $r=2$
  $a_{k+1}=\frac{a_k}{k+3}$
- Solution for $r=2$
  $\left[y=\sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y=\left(\sum_{k=0}^{\infty} a_k t^k\right)+\left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-t)\,y''+ty'-y=0$$

1.18.1 Solved as second order ode using Kovacic algorithm

Time used: 0.279 (sec)

Writing the ode as

$$(1-t)\,y''+ty'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1-t \\ B &= t \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t)=rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 4t + 6}{4\left(-1+t\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2 - 4t + 6 \\ t &= 4(-1+t)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 4t + 6}{4\left(-1+t\right)^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 31: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1+t)^2$. There is a pole at $t = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2(-1+t)} + \frac{3}{4(-1+t)^2}$$

For the pole at $t = 1$ let b be the coefficient of $\frac{1}{(-1+t)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{t^3} + \frac{11}{4t^4} + \frac{21}{4t^5} + \frac{15}{2t^6} + \frac{6}{t^7} - \frac{117}{16t^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 4t + 6}{4t^2 - 8t + 4} \\ &= Q + \frac{R}{4t^2 - 8t + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 5}{4t^2 - 8t + 4}\right) \\ &= \frac{1}{4} + \frac{-2t + 5}{4t^2 - 8t + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 4t + 6}{4\left(-1 + t\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(-1+t)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(-1+t)} + \frac{1}{2} \\
&= \frac{t-2}{2t-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(-1+t)^2}\right) + \left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right)^2 - \left(\frac{t^2-4t+6}{4(-1+t)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right) dt} \\
&= \frac{\mathrm{e}^{\frac{t}{2}}}{\sqrt{-1+t}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dt} \\
&= z_1 e^{-\int \frac{1}{2} \frac{t}{1-t} \, dt} \\
&= z_1 e^{\frac{t}{2} + \frac{\ln(-1+t)}{2}} \\
&= z_1 \left(\sqrt{-1+t}\, \mathrm{e}^{\frac{t}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{t}{1-t}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{t+\ln(-1+t)}}{(y_1)^2}\, dt \\ &= y_1 \left(-\frac{t\, e^{t+\ln(-1+t)} e^{-2t}}{-1+t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^t\right) + c_2 \left(e^t \left(-\frac{t\, e^{t+\ln(-1+t)} e^{-2t}}{-1+t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.18.2 Maple step by step solution

Let's solve

  $\frac{d}{dt}y' - \frac{ty'}{-1+t} + \frac{y}{-1+t} = 0$

□ Check to see if $t_0 = 1$ is a regular singular point

- Define functions
  $\left[P_2(t) = -\frac{t}{-1+t}, P_3(t) = \frac{1}{-1+t}\right]$
- $(-1+t) \cdot P_2(t)$ is analytic at $t = 1$
  $$\left((-1+t) \cdot P_2(t)\right)\bigg|_{t=1} = -1$$
- $(-1+t)^2 \cdot P_3(t)$ is analytic at $t = 1$
  $$\left((-1+t)^2 \cdot P_3(t)\right)\bigg|_{t=1} = 0$$
- $t = 1$is a regular singular point
  Check to see if $t_0 = 1$ is a regular singular point
  $t_0 = 1$

- Multiply by denominators
  $$(-1+t)\left(\frac{d}{dt}y'\right) - ty' + y = 0$$
- Change variables using $t = u+1$ so that the regular singular point is at $u = 0$
  $$u\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (-u-1)\left(\frac{d}{du}y(u)\right) + y(u) = 0$$
- Assume series solution for $y(u)$
  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions
- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$
  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$
- Shift index using $k- > k+1-m$
  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$
- Convert $u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion
  $$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-1}$$
- Shift index using $k- > k+1$
  $$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, u^{k+r}$$

  Rewrite ODE with series expansions
  $$a_0 r(-2+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+r-1) - a_k(k+r-1)\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)(a_{k+1}(k+1+r) - a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+1+r}$
- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{k+1}$
- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Revert the change of variables $u = -1+t$

  $\left[y = \sum_{k=0}^{\infty} a_k (-1+t)^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+3}$
- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Revert the change of variables $u = -1+t$

  $\left[y = \sum_{k=0}^{\infty} a_k (-1+t)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k (-1+t)^k\right) + \left(\sum_{k=0}^{\infty} b_k (-1+t)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$

1.19 problem 19

Internal problem ID [8157]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 19
Date solved : `Monday, October 21, 2024 at 04:54:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' + 2y = 0$$

1.19.1 Solved as second order ode using Kovacic algorithm

Time used: 0.280 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 6$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 33: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 2 \\
&= -2
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= \frac{x}{2} \qquad (10)
\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 6}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\
&= \frac{x^2}{4} - \frac{3}{2}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{3}{2}\right) - (0) \\
&= -\frac{3}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= -2 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) = 0$$

$$a_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x) \,\mathrm{e}^{\int -\frac{x}{2} dx} \\ &= (x) \,\mathrm{e}^{-\frac{x^2}{4}} \\ &= x \,\mathrm{e}^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{1} \, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x^2}{2}} x\right) + c_2\left(\mathrm{e}^{-\frac{x^2}{2}} x\left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.19.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + xy' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

- ☐ Rewrite DE with series expansions
  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert $\frac{d}{dx}y'$ to series expansion

    $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k+2$

    $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\,(k a_{k+2} + a_k + a_{k+2}) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{k+1}\right]$

1.20 problem 20

Internal problem ID [8158]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 20
Date solved : `Monday, October 21, 2024 at 04:54:38 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^{2}+1\right) y''-4 x y'+6 y=0$$

1.20.1 Solved as second order ode using Kovacic algorithm

Time used: 0.336 (sec)

Writing the ode as

$$\left(x^{2}+1\right) y''-4 x y'+6 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{2}+1 \\ B &= -4 x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A} d x}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-8}{(x^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -8$$
$$t = (x^2+1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{8}{(x^2+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 35: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{(x-i)^2} + \frac{2}{(x+i)^2} + \frac{2i}{x-i} - \frac{2i}{x+i}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{8}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	2	-1
$-i$	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x-i} + \frac{2}{x+i} + (-)\,(0) \\ &= -\frac{1}{x-i} + \frac{2}{x+i} \\ &= \frac{x-3i}{x^2+1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x-i} + \frac{2}{x+i}\right)(0) + \left(\left(\frac{1}{(x-i)^2} - \frac{2}{(x+i)^2}\right) + \left(-\frac{1}{x-i} + \frac{2}{x+i}\right)^2 - \left(-\frac{8}{(x^2+1)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{x-i} + \frac{2}{x+i}\right) dx} \\ &= \frac{(x^2+1)^2}{(ix+1)^3} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2+1}\, dx} \\ &= z_1 e^{\ln(x^2+1)} \\ &= z_1 (x^2+1) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2+1)^3}{(ix+1)^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x^2+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^2-\frac{1}{3}}{(x+i)^3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(x^2+1)^3}{(ix+1)^3}\right) + c_2 \left(\frac{(x^2+1)^3}{(ix+1)^3}\left(\frac{x^2-\frac{1}{3}}{(x+i)^3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.21 problem 21

Internal problem ID [8159]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 21
Date solved : `Monday, October 21, 2024 at 04:54:38 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-x)\,y''+xy'-y=0$$

1.21.1 Solved as second order ode using Kovacic algorithm

Time used: 0.283 (sec)

Writing the ode as

$$(1-x)\,y''+xy'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1-x \\ B &= x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 6}{4\left(-1+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 4x + 6$$
$$t = 4(-1+x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 6}{4\left(-1+x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 36: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1+x)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4(-1+x)^2} - \frac{1}{2(-1+x)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 6}{4\left(-1 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(-1+x)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(-1+x)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(-1+x)^2}\right) + \left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right)^2 - \left(\frac{x^2-4x+6}{4(-1+x)^2}\right) \right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right) dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{-1+x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{1-x} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(-1+x)}{2}} \\
&= z_1 \left(\sqrt{-1+x}\, \mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1-x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{x+\ln(-1+x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{x\, e^{x+\ln(-1+x)} e^{-2x}}{-1+x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(e^x) + c_2\left(e^x \left(-\frac{x\, e^{x+\ln(-1+x)} e^{-2x}}{-1+x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.21.2 Maple step by step solution

Let's solve

$(1-x)\left(\frac{d}{dx}y'\right) + xy' - y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{-1+x} + \frac{xy'}{-1+x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{xy'}{-1+x} + \frac{y}{-1+x} = 0$

□ Check to see if $x_0 = 1$ is a regular singular point

- Define functions
  $\left[P_2(x)=-\frac{x}{-1+x}, P_3(x)=\frac{1}{-1+x}\right]$
- $(-1+x)\cdot P_2(x)$ is analytic at $x=1$
  $$\left((-1+x)\cdot P_2(x)\right)\Big|_{x=1}=-1$$
- $(-1+x)^2\cdot P_3(x)$ is analytic at $x=1$
  $$\left((-1+x)^2\cdot P_3(x)\right)\Big|_{x=1}=0$$
- $x=1$is a regular singular point
  Check to see if $x_0=1$ is a regular singular point
  $x_0=1$

- Multiply by denominators
  $$(-1+x)\left(\frac{d}{dx}y'\right)-xy'+y=0$$
- Change variables using $x=u+1$ so that the regular singular point is at $u=0$
  $$u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$$
- Assume series solution for $y(u)$
  $$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$$
- Shift index using $k->k+1-m$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$$
- Convert $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-1}$$
- Shift index using $k->k+1$
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)\,u^{k+r}$$

  Rewrite ODE with series expansions
  $$a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k}{k+1+r}$$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{a_k}{k+1}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$$

- Revert the change of variables $u = -1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (-1+x)^k, a_{k+1} = \frac{a_k}{k+1}\right]$$

- Recursion relation for $r = 2$

$$a_{k+1} = \frac{a_k}{k+3}$$

- Solution for $r = 2$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$$

- Revert the change of variables $u = -1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (-1+x)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (-1+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (-1+x)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$$

1.22 problem 22

Internal problem ID [8160]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 22
Date solved : `Monday, October 21, 2024 at 04:54:39 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2y'' + xy' + 3y = 0$$

1.22.1 Solved as second order ode using Kovacic algorithm

Time used: 0.302 (sec)

Writing the ode as

$$2y'' + xy' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2 \\ B &= x \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 20}{16} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 20$$
$$t = 16$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{16} - \frac{5}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 38: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} - \frac{5}{2x} - \frac{25}{2x^3} - \frac{125}{x^5} - \frac{3125}{2x^7} - \frac{21875}{x^9} - \frac{328125}{x^{11}} - \frac{5156250}{x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 20}{16} \\ &= Q + \frac{R}{16} \\ &= \left(\frac{x^2}{16} - \frac{5}{4}\right) + (0) \\ &= \frac{x^2}{16} - \frac{5}{4} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{4}\right) - (0) \\ &= -\frac{5}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{4} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{4}}{\frac{1}{4}} - 1\right) &&= -3 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{4}}{\frac{1}{4}} - 1\right) &&= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{16} - \frac{5}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{4}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{4}\right) \\ &= -\frac{x}{4} \\ &= -\frac{x}{4} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{x}{4}\right)(2x + a_1) + \left(\left(-\frac{1}{4}\right) + \left(-\frac{x}{4}\right)^2 - \left(\frac{x^2}{16} - \frac{5}{4}\right)\right) = 0$$

$$2 + \frac{a_1 x}{2} + a_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -2, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega \, dx} \\
&= \left(x^2 - 2\right) \mathrm{e}^{\int -\frac{x}{4} dx} \\
&= \left(x^2 - 2\right) \mathrm{e}^{-\frac{x^2}{8}} \\
&= \left(x^2 - 2\right) \mathrm{e}^{-\frac{x^2}{8}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x}{2} \, dx} \\
&= z_1 e^{-\frac{x^2}{8}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x^2}{8}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{4}} \left(x^2 - 2\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{4}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{x^2}{4}}}{(x^2 - 2)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x^2}{4}} \left(x^2 - 2\right)\right) + c_2 \left(\mathrm{e}^{-\frac{x^2}{4}} \left(x^2 - 2\right) \left(\int \frac{\mathrm{e}^{\frac{x^2}{4}}}{\left(x^2 - 2\right)^2} dx \right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.22.2 Maple step by step solution

Let's solve

$2\frac{d}{dx}y' + xy' + 3y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{xy'}{2} - \frac{3y}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{xy'}{2} + \frac{3y}{2} = 0$

- Multiply by denominators

  $2\frac{d}{dx}y' + xy' + 3y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert $\frac{d}{dx}y'$ to series expansion

    $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k+2$

    $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

$$\sum_{k=0}^{\infty} \left(2a_{k+2}(k+2)(k+1) + a_k(k+3)\right) x^k = 0$$

- Each term in the series must be 0, giving the recursion relation
  $(2k^2 + 6k + 4)\, a_{k+2} + a_k(k+3) = 0$
- Recursion relation that defines the series solution to the ODE
  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k+3)}{2(k^2+3k+2)}\right]$

Solve

$$y'' + xy' + 2y = 0$$

1.23.1 Solved as second order ode using Kovacic algorithm

Time used: 0.245 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 6$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 40: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 6}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{3}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= -2 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) &= 0 \\ a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x) \, \mathrm{e}^{\int -\frac{x}{2} dx} \\
&= (x) \, \mathrm{e}^{-\frac{x^2}{4}} \\
&= x \, \mathrm{e}^{-\frac{x^2}{4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x}{1} \, dx} \\
&= z_1 e^{-\frac{x^2}{4}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x^2}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2} \, dx \\
&= y_1 \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x^2}{2}} x\right) + c_2\left(\mathrm{e}^{-\frac{x^2}{2}} x\left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.24 problem 24

Internal problem ID [8162]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 24
Date solved : `Monday, October 21, 2024 at 04:54:41 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-x)\,y''+xy'-y=0$$

1.24.1 Solved as second order ode using Kovacic algorithm

Time used: 0.244 (sec)

Writing the ode as

$$(1-x)\,y''+xy'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1-x \\ B &= x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 6}{4(-1+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 4x + 6 \\ t &= 4(-1+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 6}{4(-1+x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 42: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1+x)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4\,(-1+x)^2} - \frac{1}{2\,(-1+x)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{1}{2}\right) - (0)\\ &= -\frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2}\\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2}\\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 6}{4\left(-1+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = -\frac{1}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right)\\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(-1+x)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(-1+x)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(-1+x)^2}\right) + \left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right)^2 - \left(\frac{x^2-4x+6}{4(-1+x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right) dx} \\
&= \frac{e^{\frac{x}{2}}}{\sqrt{-1+x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{1-x}\, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(-1+x)}{2}} \\
&= z_1 \left(\sqrt{-1+x}\, e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1-x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(-1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{x\, e^{x+\ln(-1+x)} e^{-2x}}{-1+x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (e^x) + c_2 \left(e^x \left(-\frac{x\, e^{x+\ln(-1+x)} e^{-2x}}{-1+x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.24.2 Maple step by step solution

Let's solve

$(1-x)\left(\frac{d}{dx}y'\right) + xy' - y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{-1+x} + \frac{xy'}{-1+x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{xy'}{-1+x} + \frac{y}{-1+x} = 0$

☐ Check to see if $x_0 = 1$ is a regular singular point

- Define functions
  $\left[P_2(x) = -\frac{x}{-1+x}, P_3(x) = \frac{1}{-1+x}\right]$
- $(-1+x) \cdot P_2(x)$ is analytic at $x = 1$
  $$\left((-1+x) \cdot P_2(x)\right)\Big|_{x=1} = -1$$
- $(-1+x)^2 \cdot P_3(x)$ is analytic at $x = 1$
  $$\left((-1+x)^2 \cdot P_3(x)\right)\Big|_{x=1} = 0$$
- $x = 1$is a regular singular point
  Check to see if $x_0 = 1$ is a regular singular point
  $x_0 = 1$

• Multiply by denominators
  $(-1+x)\left(\frac{d}{dx}y'\right) - xy' + y = 0$

• Change variables using $x = u + 1$ so that the regular singular point is at $u = 0$
  $u\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (-u-1)\left(\frac{d}{du}y(u)\right) + y(u) = 0$

• Assume series solution for $y(u)$
  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions
- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$
  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$
- Shift index using $k- >k+1-m$
  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$
- Convert $u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion
  $$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-1}$$
- Shift index using $k- >k+1$
  $$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, u^{k+r}$$

  Rewrite ODE with series expansions
  $$a_0 r(-2+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(k+r-1) - a_k(k+r-1)\right) u^{k+r}\right) = 0$$

• $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k}{k+1+r}$$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{a_k}{k+1}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$$

- Revert the change of variables $u = -1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (-1+x)^k, a_{k+1} = \frac{a_k}{k+1}\right]$$

- Recursion relation for $r = 2$

$$a_{k+1} = \frac{a_k}{k+3}$$

- Solution for $r = 2$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$$

- Revert the change of variables $u = -1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (-1+x)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (-1+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (-1+x)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$$

1.25 problem 25

Internal problem ID [8163]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 25
Date solved : `Monday, October 21, 2024 at 04:54:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' + 2y = 0$$

1.25.1 Solved as second order ode using Kovacic algorithm

Time used: 0.238 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 6$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 44: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 6}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\
&= \frac{x^2}{4} - \frac{3}{2}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{3}{2}\right) - (0) \\
&= -\frac{3}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= -2 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) &= 0 \\ a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x) \, e^{\int -\frac{x}{2} dx} \\ &= (x) \, e^{-\frac{x^2}{4}} \\ &= x \, e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{1} \, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1 \left(e^{-\frac{x^2}{4}} \right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{e^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x^2}{2}} x\right) + c_2\left(\mathrm{e}^{-\frac{x^2}{2}} x\left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.25.2 Maple step by step solution

1.26 problem 26

Internal problem ID [8164]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 26
Date solved : `Monday, October 21, 2024 at 04:54:43 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(-x^2+4\right) y''+x y'+2 y=0$$

1.26.1 Solved as second order ode using Kovacic algorithm

Time used: 0.985 (sec)

Writing the ode as

$$\left(-x^2+4\right) y''+x y'+2 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^2+4 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{11x^2 - 24}{4\left(x^2 - 4\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 11x^2 - 24$$
$$t = 4\left(x^2 - 4\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{11x^2 - 24}{4\left(x^2 - 4\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 46: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 4)^2$. There is a pole at $x = 2$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{17}{32(x+2)} + \frac{17}{32(x-2)} + \frac{5}{16(x-2)^2} + \frac{5}{16(x+2)^2}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(x-2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{11x^2 - 24}{4(x^2 - 4)^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{11}{4}$. Hence

$$
\begin{aligned}
E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\
&= \{2\}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
2	2	$\{-1,2,5\}$
-2	2	$\{-1,2,5\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$
e_1 = -1,\ e_2 = -1,\ e_\infty = 2
$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$
\begin{aligned}
d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\
&= \frac{1}{2}(2-(-1+(-1))) \\
&= 2
\end{aligned}
$$

We now form the following rational function

$$
\begin{aligned}
\theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c} \\
&= \frac{1}{2}\left(\frac{-1}{(x-(2))}+\frac{-1}{(x-(-2))}\right) \\
&= -\frac{1}{2(x-2)} - \frac{1}{2(x+2)}
\end{aligned}
$$

Now we search for a monic polynomial $p(x)$ of degree $d=2$ such that

$$
p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}
$$

Since $d=2$, then letting

$$
p = x^2 + a_1 x + a_0 \tag{2A}
$$

Substituting p and θ into Eq. (1A) gives

$$\frac{11x^2 a_1 + 16(6 + a_0)\,x + 36a_1}{\left(x^2 - 4\right)^2} = 0$$

And solving for p gives

$$p = x^2 - 6$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{2x}{x^2 - 6} - \frac{1}{2\,(x - 2)} - \frac{1}{2\,(x + 2)}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{2x}{x^2 - 6} - \frac{1}{2\,(x - 2)} - \frac{1}{2\,(x + 2)}\right) w + \frac{-11x^4 + 74x^2 - 128}{4x^6 - 56x^4 + 256x^2 - 384} = 0$$

Solving for ω gives

$$\omega = \frac{2\sqrt{3}\,x^2\sqrt{x^2 - 4} + x^3 - 8\sqrt{3}\,\sqrt{x^2 - 4} - 2x}{2\left(x^2 - 6\right)(x - 2)(x + 2)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \frac{2\sqrt{3}\,x^2\sqrt{x^2-4}+x^3-8\sqrt{3}\,\sqrt{x^2-4}-2x}{2\left(x^2-6\right)(x-2)(x+2)} dx} \\ &= \frac{\sqrt{x^2 - 6}\,\left(x + \sqrt{x^2 - 4}\right)^{\sqrt{3}} \mathrm{e}^{-\frac{\operatorname{arctanh}\left(\frac{\left(\sqrt{2}\,\sqrt{3}\,x-4\right)\sqrt{2}}{2\sqrt{x^2-4}}\right)}{2} - \frac{\operatorname{arctanh}\left(\frac{\left(4+\sqrt{2}\,\sqrt{3}\,x\right)\sqrt{2}}{2\sqrt{x^2-4}}\right)}{2}}}{(x + 2)^{1/4}\,(x - 2)^{1/4}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{-x^2+4}\, dx} \\ &= z_1 e^{\frac{\ln\left(x^2-4\right)}{4}} \\ &= z_1\left(\left(x^2 - 4\right)^{1/4}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x^2-6}\left(x+\sqrt{x^2-4}\right)^{\sqrt{3}} \mathrm{e}^{-\frac{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)}{2}-\frac{\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{-x^2+4}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{\ln(x^2-4)}{2}}}{(y_1)^2}\,dx \\ &= y_1 \left(\int \frac{\sqrt{x^2-4}\left(x+\sqrt{x^2-4}\right)^{-2\sqrt{3}} \mathrm{e}^{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)+\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}}{x^2-6}dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\sqrt{x^2-6}\left(x+\sqrt{x^2-4}\right)^{\sqrt{3}} \mathrm{e}^{-\frac{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)}{2}-\frac{\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}{2}}\right) + c_2\Bigg(\sqrt{x^2-6}\,\Big(x \\ &\quad +\sqrt{x^2-4}\Big)^{\sqrt{3}} \mathrm{e}^{-\frac{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)}{2}-\frac{\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}{2}} \left(\int \frac{\sqrt{x^2-4}\left(x+\sqrt{x^2-4}\right)^{-2\sqrt{3}} \mathrm{e}^{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)+\operatorname{arctanh}}}{x^2-6}\right. \end{aligned}$$

Will add steps showing solving for IC soon.

1.26.2 Maple step by step solution

Let's solve

$(-x^2+4)\left(\frac{d}{dx}y'\right)+xy'+2y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=\frac{2y}{x^2-4}+\frac{xy'}{x^2-4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'-\frac{xy'}{x^2-4}-\frac{2y}{x^2-4}=0$

□ Check to see if x_0 is a regular singular point

 ◦ Define functions

 $\left[P_2(x)=-\frac{x}{x^2-4}, P_3(x)=-\frac{2}{x^2-4}\right]$

 ◦ $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

 $\left((x+2)\cdot P_2(x)\right)\Big|_{x=-2}=-\frac{1}{2}$

 ◦ $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

 $\left((x+2)^2\cdot P_3(x)\right)\Big|_{x=-2}=0$

 ◦ $x=-2$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-2$

- Multiply by denominators

$(x^2-4)\left(\frac{d}{dx}y'\right)-xy'-2y=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

$(u^2-4u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-u+2)\left(\frac{d}{du}y(u)\right)-2y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

 ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

 $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

 ◦ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- ○ Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- ○ Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0r(-3+2r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)\,(2k-1+2r) + a_k(k^2+2kr+r^2-2k-2r-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2r(-3+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{3}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-4\left(k-\frac{1}{2}+r\right)(k+1+r)\,a_{k+1} + \left(k^2+(2r-2)\,k+r^2-2r-2\right)a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{(k^2+2kr+r^2-2k-2r-2)\,a_k}{2(2k-1+2r)(k+1+r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{(k^2-2k-2)\,a_k}{2(2k-1)(k+1)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{(k^2-2k-2)\,a_k}{2(2k-1)(k+1)}\right]$$

- Revert the change of variables $u = x+2$

$$\left[y = \sum_{k=0}^{\infty} a_k(x+2)^k, a_{k+1} = \frac{(k^2-2k-2)\,a_k}{2(2k-1)(k+1)}\right]$$

- Recursion relation for $r = \frac{3}{2}$

$$a_{k+1} = \frac{\left(k^2+k-\frac{11}{4}\right)a_k}{2(2k+2)\left(k+\frac{5}{2}\right)}$$

- Solution for $r = \frac{3}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{3}{2}}, a_{k+1} = \frac{\left(k^2+k-\frac{11}{4}\right)a_k}{2(2k+2)\left(k+\frac{5}{2}\right)}\right]$$

- Revert the change of variables $u = x+2$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+2)^{k+\frac{3}{2}}, a_{k+1} = \frac{\left(k^2+k-\frac{11}{4}\right) a_k}{2(2k+2)\left(k+\frac{5}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (x+2)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x+2)^{k+\frac{3}{2}}\right), a_{k+1} = \frac{(k^2-2k-2) a_k}{2(2k-1)(k+1)}, b_{k+1} = \frac{\left(k^2+k-\frac{11}{4}\right) b_k}{2(2k+2)\left(k+\frac{5}{2}\right)}\right]$$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' - 4xy' + \left(-16x^2+3\right) y = 0$$

1.27.1 Solved as second order ode using Kovacic algorithm

Time used: 0.112 (sec)

Writing the ode as

$$4x^2y'' - 4xy' + \left(-16x^2+3\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= -16x^2+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 48: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-2x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \sqrt{x}\,\mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\,\mathrm{e}^{-2x}\right) + c_2\left(\sqrt{x}\,\mathrm{e}^{-2x}\left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.27.2 Maple step by step solution

Let's solve

$4x^2\left(\frac{d}{dx}y'\right) - 4xy' + \left(-16x^2 + 3\right)y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(16x^2-3)y}{4x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{y'}{x} - \frac{(16x^2-3)y}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{1}{x}, P_3(x) = -\frac{16x^2-3}{4x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{3}{4}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d}{dx}y'\right) - 4xy' + \left(-16x^2 + 3\right)y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot y'$ to series expansion

  $$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $$x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+2r)\,(-3+2r)\, x^r + a_1(1+2r)\,(-1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r-1)\,(2k+2r-3) - 1$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+2r)\,(-3+2r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{\frac{1}{2}, \frac{3}{2}\right\}$$

- Each term must be 0

  $$a_1(1+2r)\,(-1+2r) = 0$$

- Solve for the dependent coefficient(s)

  $$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$4\left(k+r-\frac{1}{2}\right)\left(k+r-\frac{3}{2}\right) a_k - 16a_{k-2} = 0$$

- Shift index using $k- >k+2$

  $$4\left(k+\frac{3}{2}+r\right)\left(k+\frac{1}{2}+r\right) a_{k+2} - 16a_k = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = \frac{16a_k}{(2k+3+2r)(2k+1+2r)}$$

- Recursion relation for $r = \frac{1}{2}$

  $$a_{k+2} = \frac{16a_k}{(2k+4)(2k+2)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty} a_{k} x^{k+\frac{1}{2}}, a_{k+2}=\frac{16 a_{k}}{(2 k+4)(2 k+2)}, a_{1}=0\right]$$

- Recursion relation for $r=\frac{3}{2}$

$$a_{k+2}=\frac{16 a_{k}}{(2 k+6)(2 k+4)}$$

- Solution for $r=\frac{3}{2}$

$$\left[y=\sum_{k=0}^{\infty} a_{k} x^{k+\frac{3}{2}}, a_{k+2}=\frac{16 a_{k}}{(2 k+6)(2 k+4)}, a_{1}=0\right]$$

1.28 problem 28

Internal problem ID [8166]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 28
Date solved : `Monday, October 21, 2024 at 04:54:45 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(x-1)\, y'' - x y' + y = 0$$

1.28.1 Solved as second order ode using Kovacic algorithm

Time used: 0.249 (sec)

Writing the ode as

$$(x-1)\, y'' - x y' + y = 0 \tag{1}$$
$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x-1 \\ B &= -x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 6}{4(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 4x + 6$$
$$t = 4(x-1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 6}{4(x-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 50: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

<u>Attempting to find a solution using case $n = 1$.</u>

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2(x-1)} + \frac{3}{4(x-1)^2}$$

For the <u>pole at $x = 1$</u> let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 6}{4(x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(x-1)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(x-1)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(x-1)^2}\right) + \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)^2 - \left(\frac{x^2 - 4x + 6}{4(x-1)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right) dx} \\
&= \frac{e^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-x}{x-1} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x-1)}{2}} \\
&= z_1 \left(\sqrt{x-1}\, e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x-1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{x\, e^{x+\ln(x-1)} e^{-2x}}{x-1}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(e^x) + c_2 \left(e^x \left(-\frac{x\, e^{x+\ln(x-1)} e^{-2x}}{x-1}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.28.2 Maple step by step solution

Let's solve

$(x-1)\left(\frac{d}{dx}y'\right) - xy' + y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{x-1} + \frac{xy'}{x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{xy'}{x-1} + \frac{y}{x-1} = 0$

□ Check to see if $x_0 = 1$ is a regular singular point

- Define functions
  $\left[P_2(x) = -\frac{x}{x-1}, P_3(x) = \frac{1}{x-1}\right]$
- $(x-1)\cdot P_2(x)$ is analytic at $x=1$
  $$\left((x-1)\cdot P_2(x)\right)\bigg|_{x=1} = -1$$
- $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$
  $$\left((x-1)^2\cdot P_3(x)\right)\bigg|_{x=1} = 0$$
- $x=1$is a regular singular point
  Check to see if $x_0 = 1$ is a regular singular point
  $x_0 = 1$

- Multiply by denominators
  $(x-1)\left(\frac{d}{dx}y'\right) - xy' + y = 0$
- Change variables using $x = u+1$ so that the regular singular point is at $u=0$
  $u\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (-u-1)\left(\frac{d}{du}y(u)\right) + y(u) = 0$
- Assume series solution for $y(u)$
  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$
- Shift index using $k->k+1-m$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$
- Convert $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-1}$$
- Shift index using $k->k+1$
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\,u^{k+r}$$
  Rewrite ODE with series expansions
  $$a_0 r(-2+r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)(k+r-1) - a_k(k+r-1)\right)u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r)=0$

- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_{k+1}(k+1+r)-a_k\right)=0$

1.29 problem 29

Internal problem ID [8167]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 29
Date solved : `Monday, October 21, 2024 at 04:54:46 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2xy' + (x^2+2)\,y = 0$$

1.29.1 Solved as second order ode using Kovacic algorithm

Time used: 0.145 (sec)

Writing the ode as

$$x^2y'' - 2xy' + (x^2+2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 52: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (x \cos(x)) + c_2 (x \cos(x) (\tan(x)))
\end{aligned}
$$

Will add steps showing solving for IC soon.

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -2$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 2$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $x^2 \left(\frac{d}{dx} y'\right) - 2xy' + (x^2 + 2) y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)\,(-2+r)\, x^r + a_1 r(-1+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)\,(k+r-2) + a_{k-2}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 2\}$

- Each term must be 0

  $a_1 r(-1+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-1)\,(k+r-2) + a_{k-2} = 0$

- Shift index using $k- >k + 2$

  $a_{k+2}(k+1+r)\,(k+r) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+1+r)(k+r)}$

- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k}{(k+2)(k+1)}$

- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$

- Recursion relation for $r = 2$

$$a_{k+2} = -\frac{a_k}{(k+3)(k+2)}$$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = -\frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$$

1.30 problem 31

Internal problem ID [8168]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 31
Date solved : `Monday, October 21, 2024 at 04:54:47 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2-2x\right)y''+\left(-x^2+2\right)y'+\left(2x-2\right)y=0$$

1.30.1 Solved as second order ode using Kovacic algorithm

Time used: 0.316 (sec)

Writing the ode as

$$\left(x^2-2x\right)y''+\left(-x^2+2\right)y'+\left(2x-2\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-2x \\ B &= -x^2+2 \\ C &= 2x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4(x^2 - 2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^4 - 8x^3 + 24x^2 - 24x + 12$$
$$t = 4(x^2 - 2x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4(x^2 - 2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 54: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{4(x-2)} + \frac{3}{4(x-2)^2} - \frac{3}{4x} + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(x-2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{2}{x^3} + \frac{11}{x^4} + \frac{42}{x^5} + \frac{132}{x^6} + \frac{348}{x^7} + \frac{711}{x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading

coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2} \\
&= Q + \frac{R}{4x^4 - 16x^3 + 16x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}\right) \\
&= \frac{1}{4} + \frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}
\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned}
b &= (-1) - (0) \\
&= -1
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &= -1 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to

determine possible non negative integer d from these using

$$d = \alpha_{\infty}^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_{\infty}^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_{\infty}^{+} = -1$ then

$$\begin{aligned} d &= \alpha_{\infty}^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{-}\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2} \right) + (+)[\sqrt{r}]_{\infty} \\ &= -\frac{1}{2x} - \frac{1}{2\left(x-2\right)} + \left(\frac{1}{2}\right) \\ &= -\frac{1}{2x} - \frac{1}{2\left(x-2\right)} + \frac{1}{2} \\ &= -\frac{1}{2x} - \frac{1}{2x-4} + \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x} - \frac{1}{2\left(x-2\right)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2x^2} + \frac{1}{2\left(x-2\right)^2}\right) + \left(-\frac{1}{2x} - \frac{1}{2\left(x-2\right)} + \frac{1}{2}\right)^2 - \left(\frac{x^4 - 8x^3 +}{4(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right) dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-2}\,\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+2}{x^2-2x} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x-2)}{2} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{x}}{\sqrt{x\,(x-2)}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^2-2x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{x+\ln(x-2)+\ln(x)}}{(y_1)^2} \, dx \\
&= y_1 \left(-\frac{x\,\mathrm{e}^{x+\ln(x-2)+\ln(x)}\mathrm{e}^{-2x}}{x-2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{x}}{\sqrt{x\,(x-2)}}\right) + c_2 \left(\frac{\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{x}}{\sqrt{x\,(x-2)}} \left(-\frac{x\,\mathrm{e}^{x+\ln(x-2)+\ln(x)}\mathrm{e}^{-2x}}{x-2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.30.2 Maple step by step solution

Let's solve

$(x^2-2x)\left(\frac{d}{dx}y'\right)+(-x^2+2)\,y'+(2x-2)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{2(x-1)y}{x(x-2)}+\frac{(x^2-2)y'}{x(x-2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'-\frac{(x^2-2)y'}{x(x-2)}+\frac{2(x-1)y}{x(x-2)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{x^2-2}{x(x-2)},P_3(x)=\frac{2(x-1)}{x(x-2)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=-1$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x(x-2)\left(\frac{d}{dx}y'\right)+(-x^2+2)\,y'+(2x-2)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y$ to series expansion for $m=0..1$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx} y'\right)$ to series expansion for $m = 1..2$

$$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0 r(-2+r)\, x^{-1+r} + \left(-2a_1(1+r)\,(-1+r) + a_0(1+r)\,(-2+r)\right) x^r + \left(\sum_{k=1}^{\infty} \left(-2a_{k+1}(k+r+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-2r(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term must be 0
  $-2a_1(1+r)\,(-1+r) + a_0(1+r)\,(-2+r) = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_k(k+r+1)\,(k+r-2) - 2k^2 a_{k+1} + (-4r a_{k+1} - a_{k-1})\, k - 2r^2 a_{k+1} - a_{k-1} r + 3a_{k-1} + 2a_{k+1} =$
- Shift index using $k- >k+1$
  $a_{k+1}(k+2+r)\,(k+r-1) - 2(k+1)^2 a_{k+2} + (-4r a_{k+2} - a_k)\,(k+1) - 2r^2 a_{k+2} - r a_k + 3a_k +$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{k^2 a_{k+1} + 2kr a_{k+1} + r^2 a_{k+1} - k a_k + k a_{k+1} - r a_k + r a_{k+1} + 2a_k - 2a_{k+1}}{2(k^2 + 2kr + r^2 + 2k + 2r)}$
- Recursion relation for $r = 0$
  $a_{k+2} = \frac{k^2 a_{k+1} - k a_k + k a_{k+1} + 2a_k - 2a_{k+1}}{2(k^2 + 2k)}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$
  $a_{k+2} = \frac{k^2 a_{k+1} - k a_k + k a_{k+1} + 2a_k - 2a_{k+1}}{2(k^2 + 2k)}$
- Recursion relation for $r = 2$

$$a_{k+2} = \frac{k^2 a_{k+1} - k a_k + 5k a_{k+1} + 4a_{k+1}}{2(k^2+6k+8)}$$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{k^2 a_{k+1} - k a_k + 5k a_{k+1} + 4a_{k+1}}{2(k^2+6k+8)}, -6a_1 = 0\right]$$

1.31 problem 32

Internal problem ID [8169]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 32
Date solved : `Monday, October 21, 2024 at 04:54:48 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + \left(-8x^2 + 4x\right) y' + \left(4x^2 - 4x - 1\right) y = 0$$

1.31.1 Solved as second order ode using Kovacic algorithm

Time used: 0.112 (sec)

Writing the ode as

$$4x^2y'' + \left(-8x^2 + 4x\right) y' + \left(4x^2 - 4x - 1\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -8x^2 + 4x \\ C &= 4x^2 - 4x - 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{0}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 0 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 0 \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 56: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-8x^2+4x}{4x^2}\,dx} \\ &= z_1 e^{x-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{e^x}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^x}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-8x^2+4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x-\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^x}{\sqrt{x}}\right) + c_2 \left(\frac{e^x}{\sqrt{x}}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.31.2 Maple step by step solution

Let's solve

$4x^2\left(\frac{d}{dx}y'\right) + (-8x^2 + 4x)\, y' + (4x^2 - 4x - 1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(4x^2-4x-1)y}{4x^2} + \frac{(2x-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{(2x-1)y'}{x} + \frac{(4x^2-4x-1)y}{4x^2} = 0$

- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{2x-1}{x}, P_3(x) = \frac{4x^2-4x-1}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{1}{4}$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d}{dx}y'\right) - 4x(2x - 1)\, y' + (4x^2 - 4x - 1)\, y = 0$

- Assume series solution for y

$$y=\sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

$$x^m \cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k->k-m$

$$x^m \cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$$x^m \cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

$$x^2 \cdot \left(\frac{d}{dx}y'\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+2r)\,(-1+2r)\, x^r+\left(a_1(3+2r)\,(1+2r)-4a_0(1+2r)\right) x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(2k+2r+1)\,(2k\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+2r)\,(-1+2r)=0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term must be 0
  $a_1(3+2r)\,(1+2r)-4a_0(1+2r)=0$
- Solve for the dependent coefficient(s)
  $a_1=\frac{4a_0}{3+2r}$
- Each term in the series must be 0, giving the recursion relation
  $a_k(4k^2+8kr+4r^2-1)+(-8k-8r+4)\,a_{k-1}+4a_{k-2}=0$
- Shift index using $k->k+2$
  $a_{k+2}\left(4(k+2)^2+8(k+2)\,r+4r^2-1\right)+(-8k-12-8r)\,a_{k+1}+4a_k=0$
- Recursion relation that defines series solution to ODE
  $a_{k+2}=\frac{4(2ka_{k+1}+2ra_{k+1}-a_k+3a_{k+1})}{4k^2+8kr+4r^2+16k+16r+15}$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = \frac{4(2ka_{k+1}-a_k+2a_{k+1})}{4k^2+12k+8}$
- Solution for $r = -\frac{1}{2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = \frac{4(2ka_{k+1}-a_k+2a_{k+1})}{4k^2+12k+8}, a_1 = 2a_0\right]$$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = \frac{4(2ka_{k+1}-a_k+4a_{k+1})}{4k^2+20k+24}$
- Solution for $r = \frac{1}{2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{4(2ka_{k+1}-a_k+4a_{k+1})}{4k^2+20k+24}, a_1 = a_0\right]$$
- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = \frac{4(2ka_{k+1}-a_k+2a_{k+1})}{4k^2+12k+8}, a_1 = 2a_0, b_{k+2} = \frac{4(2kb_{k+1}-b_k+4b_{k+1}}{4k^2+20k+24}\right.$$

1.32 problem 33

Internal problem ID [8170]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 33
Date solved : `Monday, October 21, 2024 at 04:54:49 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0$$

1.32.1 Solved as second order ode using Kovacic algorithm

Time used: 0.085 (sec)

Writing the ode as

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4x \\ C &= 4x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 58: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x}{1}\,dx} \\
&= z_1 e^{-x^2} \\
&= z_1 \left(\mathrm{e}^{-x^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x^2}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x^2}\right) + c_2 \left(\mathrm{e}^{-x^2}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.32.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + 4xy' + (4x^2 + 2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ○ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ○ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

- ○ Convert $\frac{d}{dx}y'$ to series expansion

  $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ○ Shift index using $k- >k + 2$

  $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$2a_2 + 2a_0 + (6a_3 + 6a_1)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) + 2a_k(2k+1) + 4a_{k-2})\, x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 + 2a_0 = 0, 6a_3 + 6a_1 = 0]$
- Solve for the dependent coefficient(s)

  $\{a_2 = -a_0, a_3 = -a_1\}$
- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} + 4a_k k + 2a_k + 4a_{k-2} = 0$
- Shift index using $k- >k + 2$

  $\left((k+2)^2 + 3k + 8\right) a_{k+4} + 4a_{k+2}(k+2) + 2a_{k+2} + 4a_k = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{2(2ka_{k+2}+2a_k+5a_{k+2})}{k^2+7k+12}, a_2 = -a_0, a_3 = -a_1\right]$

1.33 problem 34

Internal problem ID [8171]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 34
Date solved : `Monday, October 21, 2024 at 04:54:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2x+1)\,y''-2y'-(2x+3)\,y=0$$

1.33.1 Solved as second order ode using Kovacic algorithm

Time used: 0.236 (sec)

Writing the ode as

$$(2x+1)\,y''-2y'+(-2x-3)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x+1\\B&=-2\\C&=-2x-3\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 + 8x + 6}{(2x+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4x^2 + 8x + 6$$
$$t = (2x+1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 + 8x + 6}{(2x+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 60: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x+1)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{3}{4\left(x + \frac{1}{2}\right)^2} + \frac{1}{x + \frac{1}{2}}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{2x} - \frac{1}{4x^3} + \frac{11}{32x^4} - \frac{21}{64x^5} + \frac{15}{64x^6} - \frac{3}{32x^7} - \frac{117}{2048x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 8x + 6}{4x^2 + 4x + 1} \\ &= Q + \frac{R}{4x^2 + 4x + 1} \\ &= (1) + \left(\frac{4x + 5}{4x^2 + 4x + 1}\right) \\ &= 1 + \frac{4x + 5}{4x^2 + 4x + 1} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 1 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{1}{1} - 0\right) &&= \frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{1}{1} - 0\right) &&= -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^2 + 8x + 6}{(2x + 1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	1	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2\left(x + \frac{1}{2}\right)} + (-)(1) \\
&= -\frac{1}{2\left(x + \frac{1}{2}\right)} - 1 \\
&= -\frac{2(x+1)}{2x+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right)(0) + \left(\left(\frac{1}{2\left(x + \frac{1}{2}\right)^2}\right) + \left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right)^2 - \left(\frac{4x^2 + 8x + 6}{(2x+1)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right) dx} \\
&= \frac{\mathrm{e}^{-x}}{\sqrt{2x+1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-2}{2x+1} \, dx} \\
&= z_1 e^{\frac{\ln(2x+1)}{2}} \\
&= z_1 \left(\sqrt{2x+1}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{2x+1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\ln(2x+1)}}{(y_1)^2}\, dx \\ &= y_1 \left(x\,\mathrm{e}^{2x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(x\,\mathrm{e}^{2x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.33.2 Maple step by step solution

Let's solve
$(2x+1)\left(\frac{d}{dx}y'\right) - 2y' - (2x+3)\,y = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d}{dx}y'$
- Isolate 2nd derivative
  $\frac{d}{dx}y' = \frac{(2x+3)y}{2x+1} + \frac{2y'}{2x+1}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d}{dx}y' - \frac{2y'}{2x+1} - \frac{(2x+3)y}{2x+1} = 0$

□ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{2}{2x+1}, P_3(x) = -\frac{2x+3}{2x+1}\right]$

- $\left(x+\frac{1}{2}\right)\cdot P_2(x)$ is analytic at $x=-\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right)\cdot P_2(x)\right)\bigg|_{x=-\frac{1}{2}}=-1$

- $\left(x+\frac{1}{2}\right)^2\cdot P_3(x)$ is analytic at $x=-\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right)^2\cdot P_3(x)\right)\bigg|_{x=-\frac{1}{2}}=0$

- $x=-\frac{1}{2}$is a regular singular point

  Check to see if $x_0=-\frac{1}{2}$ is a regular singular point

  $x_0=-\frac{1}{2}$

- Multiply by denominators

  $(2x+1)\left(\frac{d}{dx}y'\right)-2y'+(-2x-3)\,y=0$

- Change variables using $x=u-\frac{1}{2}$ so that the regular singular point is at $u=0$

  $2u\left(\frac{d}{du}\frac{d}{du}y(u)\right)-2\frac{d}{du}y(u)+(-2u-2)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- Convert $\frac{d}{du}y(u)$ to series expansion

  $\frac{d}{du}y(u)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1}$

- Shift index using $k->k+1$

  $\frac{d}{du}y(u)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,u^{k+r}$

- Convert $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- Shift index using $k->k+1$

$$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$2a_0 r(-2+r)\,u^{-1+r} + (2a_1(1+r)\,(-1+r) - 2a_0)\,u^r + \left(\sum_{k=1}^{\infty} (2a_{k+1}(k+1+r)\,(k+r-1) - 2a_k\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $2r(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$
- Each term must be 0

  $2a_1(1+r)\,(-1+r) - 2a_0 = 0$
- Each term in the series must be 0, giving the recursion relation

  $2a_{k+1}(k+1+r)\,(k+r-1) - 2a_k - 2a_{k-1} = 0$
- Shift index using $k- >k+1$

  $2a_{k+2}(k+2+r)\,(k+r) - 2a_{k+1} - 2a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2+r)(k+r)}$
- Recursion relation for $r = 0$

  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2)k}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2)k}$
- Recursion relation for $r = 2$

  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}$
- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}, 6a_1 - 2a_0 = 0\right]$
- Revert the change of variables $u = x + \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k \left(x + \frac{1}{2}\right)^{k+2}, a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}, 6a_1 - 2a_0 = 0\right]$

1.34 problem 35

Internal problem ID [8172]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 35
Date solved : `Monday, October 21, 2024 at 04:54:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$xy'' - (2x+2)\,y' + (x+2)\,y = 0$$

1.34.1 Solved as second order ode using Kovacic algorithm

Time used: 0.154 (sec)

Writing the ode as

$$xy'' + (-2x-2)\,y' + (x+2)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -2x-2 \\ C &= x+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2$$
$$t = x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 62: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2}{x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x} + (-)\,(0) \\
&= -\frac{1}{x} \\
&= -\frac{1}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{1}{x} dx} \\ &= \frac{1}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-2x-2}{x} \, dx} \\ &= z_1 e^{x+\ln(x)} \\ &= z_1(x \, \mathrm{e}^x) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x-2}{x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{2x+2\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{x \, \mathrm{e}^{2x+2\ln(x)} \mathrm{e}^{-2x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2\left(\mathrm{e}^x\left(\frac{x\,\mathrm{e}^{2x+2\ln(x)}\mathrm{e}^{-2x}}{3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.35 problem 36

Internal problem ID [8173]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 36
Date solved : `Monday, October 21, 2024 at 04:54:51 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2xy' + \left(x^2+2\right)y = 0$$

1.35.1 Solved as second order ode using Kovacic algorithm

Time used: 0.149 (sec)

Writing the ode as

$$x^2y'' - 2xy' + \left(x^2+2\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 64: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\cos(x)) + c_2(x\cos(x)(\tan(x)))
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.35.2 Maple step by step solution

Let's solve

$x^2\left(\frac{d}{dx}y'\right) - 2xy' + (x^2+2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(x^2+2)y}{x^2} + \frac{2y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{2y'}{x} + \frac{(x^2+2)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{2}{x}, P_3(x) = \frac{x^2+2}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = -2$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = 2$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d}{dx}y'\right) - 2xy' + (x^2+2)\,y = 0$

- Assume series solution for y

1.36 problem 38

Internal problem ID [8174]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 38
Date solved : `Monday, October 21, 2024 at 04:54:52 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' - 4xy' + \left(-16x^2 + 3\right) y = 0$$

1.36.1 Solved as second order ode using Kovacic algorithm

Time used: 0.113 (sec)

Writing the ode as

$$4x^2y'' - 4xy' + \left(-16x^2 + 3\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= -16x^2 + 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 66: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\,dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\,\mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\, \mathrm{e}^{-2x}\right) + c_2\left(\sqrt{x}\, \mathrm{e}^{-2x}\left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.36.2 Maple step by step solution

Let's solve

$4x^2\left(\frac{d}{dx}y'\right) - 4xy' + \left(-16x^2+3\right)y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

1.37 problem 39

Internal problem ID [8175]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 39
Date solved : `Monday, October 21, 2024 at 04:54:53 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' - 4xy' + \left(4x^2+3\right)y = 0$$

1.37.1 Solved as second order ode using Kovacic algorithm

Time used: 0.191 (sec)

Writing the ode as

$$4x^2y'' - 4xy' + \left(4x^2+3\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= 4x^2+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 68: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\,dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\,\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\, \cos(x)\right) + c_2\left(\sqrt{x}\, \cos(x)\,(\tan(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.37.2 Maple step by step solution

Let's solve

$4x^2\left(\frac{d}{dx}y'\right) - 4xy' + (4x^2+3)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(4x^2+3)y}{4x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{y'}{x} + \frac{(4x^2+3)y}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

1.38 problem 40

Internal problem ID [8176]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 40
Date solved : `Monday, October 21, 2024 at 04:54:54 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2xy' - \left(x^2 - 2\right) y = 0$$

1.38.1 Solved as second order ode using Kovacic algorithm

Time used: 0.091 (sec)

Writing the ode as

$$x^2y'' - 2xy' + \left(-x^2 + 2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= -x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 70: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x\,\mathrm{e}^{-x}\right) + c_2 \left(x\,\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.38.2 Maple step by step solution

Let's solve

$x^2 \left(\frac{d}{dx} y'\right) - 2xy' - \left(x^2 - 2\right) y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$

- Isolate 2nd derivative

  $\frac{d}{dx} y' = \frac{(x^2-2)y}{x^2} + \frac{2y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx} y' - \frac{2y'}{x} - \frac{(x^2-2)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{2}{x}, P_3(x) = -\frac{x^2-2}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -2$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 2$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2 \left(\frac{d}{dx} y'\right) - 2xy' + \left(-x^2 + 2\right) y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot y'$ to series expansion

$$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

$$x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+r)\,(-2+r)\,x^r + a_1 r(-1+r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)\,(k+r-2) - a_{k-2}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 2\}$

- Each term must be 0

  $a_1 r(-1+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-1)\,(k+r-2) - a_{k-2} = 0$

- Shift index using $k->k+2$

  $a_{k+2}(k+1+r)\,(k+r) - a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k}{(k+1+r)(k+r)}$

- Recursion relation for $r = 1$

  $a_{k+2} = \frac{a_k}{(k+2)(k+1)}$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = \frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$$

- Recursion relation for $r = 2$

$a_{k+2} = \frac{a_k}{(k+3)(k+2)}$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+2} = \frac{a_k}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = \frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$$

Section : section 1
Problem number : 41
Date solved : `Monday, October 21, 2024 at 04:54:54 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2x(x+1)\,y' + \left(x^2+2x+2\right)y = 0$$

1.39.1 Solved as second order ode using Kovacic algorithm

Time used: 0.109 (sec)

Writing the ode as

$$x^2y'' + \left(-2x^2-2x\right)y' + \left(x^2+2x+2\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^2-2x \\ C &= x^2+2x+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 72: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x^2-2x}{x^2}\, dx} \\
&= z_1 e^{x+\ln(x)} \\
&= z_1 (x\, \mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$
y_1 = x\, \mathrm{e}^{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-2x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2x+2\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\,\mathrm{e}^x) + c_2(x\,\mathrm{e}^x(x))
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.39.2 Maple step by step solution

Let's solve

$x^2\left(\frac{d}{dx}y'\right) - 2x(x+1)\,y' + (x^2+2x+2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

1.40 problem 42

Internal problem ID [8178]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 42
Date solved : `Monday, October 21, 2024 at 04:54:55 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2x(x+2)\,y' + \left(x^2+4x+6\right)y = 0$$

1.40.1 Solved as second order ode using Kovacic algorithm

Time used: 0.097 (sec)

Writing the ode as

$$x^2y'' + \left(-2x^2-4x\right)y' + \left(x^2+4x+6\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^2-4x \\ C &= x^2+4x+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 74: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x^2-4x}{x^2}\,dx} \\ &= z_1 e^{x+2\ln(x)} \\ &= z_1\left(x^2 e^x\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x+4\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^2 \mathrm{e}^x\right) + c_2 \left(x^2 \mathrm{e}^x (x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.40.2 Maple step by step solution

Let's solve

$x^2 \left(\frac{d}{dx} y'\right) - 2x(x+2)\, y' + \left(x^2+4x+6\right) y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$

- Isolate 2nd derivative

  $\frac{d}{dx} y' = -\frac{\left(x^2+4x+6\right) y}{x^2} + \frac{2(x+2) y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx} y' - \frac{2(x+2) y'}{x} + \frac{\left(x^2+4x+6\right) y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{2(x+2)}{x}, P_3(x) = \frac{x^2+4x+6}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.\left(x \cdot P_2(x)\right)\right|_{x=0} = -4$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.\left(x^2 \cdot P_3(x)\right)\right|_{x=0} = 6$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2 \left(\frac{d}{dx} y'\right) - 2x(x+2)\, y' + \left(x^2+4x+6\right) y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- > k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
  - Shift index using $k- > k + 1 - m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$
  - Convert $x^2 \cdot \left(\frac{d}{dx} y'\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)\,(-3+r)\, x^r + (a_1(-1+r)\,(-2+r) - 2a_0(-2+r))\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r-2)\,(k+$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)\,(-3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{2, 3\}$
- Each term must be 0

  $a_1(-1+r)\,(-2+r) - 2a_0(-2+r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = \frac{2a_0}{-1+r}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)\,(k+r-3) - 2a_{k-1}k - 2a_{k-1}r + a_{k-2} + 6a_{k-1} = 0$
- Shift index using $k- > k + 2$

  $a_{k+2}(k+r)\,(k+r-1) - 2a_{k+1}(k+2) - 2a_{k+1}r + a_k + 6a_{k+1} = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{2ka_{k+1} + 2a_{k+1}r - a_k - 2a_{k+1}}{(k+r)(k+r-1)}$
- Recursion relation for $r = 2$

  $a_{k+2} = \frac{2ka_{k+1} - a_k + 2a_{k+1}}{(k+2)(k+1)}$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{2k a_{k+1} - a_k + 2a_{k+1}}{(k+2)(k+1)}, a_1 = 2a_0\right]$$

- Recursion relation for $r = 3$

$$a_{k+2} = \frac{2k a_{k+1} - a_k + 4a_{k+1}}{(k+3)(k+2)}$$

- Solution for $r = 3$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = \frac{2k a_{k+1} - a_k + 4a_{k+1}}{(k+3)(k+2)}, a_1 = a_0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), a_{k+2} = \frac{2k a_{k+1} - a_k + 2a_{k+1}}{(k+2)(k+1)}, a_1 = 2a_0, b_{k+2} = \frac{2k b_{k+1} - b_k + 4b_{k+1}}{(k+3)(k+2)}, b_1 =$$

1.41 problem 43

Internal problem ID [8179]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 43
Date solved : `Monday, October 21, 2024 at 04:54:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 4xy' + (x^2+6)\, y = 0$$

1.41.1 Solved as second order ode using Kovacic algorithm

Time used: 0.149 (sec)

Writing the ode as

$$x^2y'' - 4xy' + (x^2+6)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= x^2+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 76: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\,dx} \\
&= z_1 e^{2\ln(x)} \\
&= z_1 \left(x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2 \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x^2 \cos(x)\right) + c_2\left(x^2 \cos(x)\left(\tan(x)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.41.2 Maple step by step solution

Let's solve

$x^2\left(\frac{d}{dx}y'\right) - 4xy' + \left(x^2+6\right)y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$
- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(x^2+6)y}{x^2} + \frac{4y'}{x}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{4y'}{x} + \frac{(x^2+6)y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = -\frac{4}{x}, P_3(x) = \frac{x^2+6}{x^2}\right]$
- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -4$
- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 6$
- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d}{dx}y'\right) - 4xy' + \left(x^2+6\right)y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)\,(-3+r)\, x^r + a_1(-1+r)\,(-2+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r-2)\,(k+r-3) + a_{k-2})\, x^{k}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)\,(-3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{2, 3\}$

- Each term must be 0

  $a_1(-1+r)\,(-2+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)\,(k+r-3) + a_{k-2} = 0$

- Shift index using $k- >k+2$

  $a_{k+2}(k+r)\,(k+r-1) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+r)(k+r-1)}$

- Recursion relation for $r = 2$

  $a_{k+2} = -\frac{a_k}{(k+2)(k+1)}$

- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$

- Recursion relation for $r = 3$

$a_{k+2} = -\frac{a_k}{(k+3)(k+2)}$

- Solution for $r = 3$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = -\frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = -\frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$

1.42 problem 44

Internal problem ID [8180]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 44
Date solved : `Monday, October 21, 2024 at 04:54:57 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(x-1)\,y''-xy'+y=0$$

1.42.1 Solved as second order ode using Kovacic algorithm

Time used: 0.245 (sec)

Writing the ode as

$$(x-1)\,y''-xy'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x-1\\ B &= -x\\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 6}{4(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 4x + 6$$
$$t = 4(x-1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 6}{4(x-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 78: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2(x-1)} + \frac{3}{4(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 6}{4(x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(x-1)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(x-1)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(x-1)^2}\right) + \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)^2 - \left(\frac{x^2 - 4x + 6}{4(x-1)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right) dx} \\
&= \frac{e^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-x}{x-1} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x-1)}{2}} \\
&= z_1 \left(\sqrt{x-1}\, e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x-1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{x\, \mathrm{e}^{x+\ln(x-1)} \mathrm{e}^{-2x}}{x-1}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\mathrm{e}^{x}) + c_2\left(\mathrm{e}^{x}\left(-\frac{x\, \mathrm{e}^{x+\ln(x-1)} \mathrm{e}^{-2x}}{x-1}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.42.2 Maple step by step solution

Let's solve

$(x-1)\left(\frac{d}{dx}y'\right) - xy' + y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{x-1} + \frac{xy'}{x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{xy'}{x-1} + \frac{y}{x-1} = 0$

□ Check to see if $x_0 = 1$ is a regular singular point

- Define functions
  $\left[P_2(x) = -\frac{x}{x-1}, P_3(x) = \frac{1}{x-1}\right]$
- $(x-1)\cdot P_2(x)$ is analytic at $x=1$
  $$\left((x-1)\cdot P_2(x)\right)\Bigg|_{x=1} = -1$$
- $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$
  $$\left((x-1)^2\cdot P_3(x)\right)\Bigg|_{x=1} = 0$$
- $x=1$is a regular singular point
  Check to see if $x_0 = 1$ is a regular singular point
  $x_0 = 1$

- Multiply by denominators
  $(x-1)\left(\frac{d}{dx}y'\right) - xy' + y = 0$
- Change variables using $x = u+1$ so that the regular singular point is at $u=0$
  $u\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (-u-1)\left(\frac{d}{du}y(u)\right) + y(u) = 0$
- Assume series solution for $y(u)$
  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions
- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$
- Shift index using $k->k+1-m$
  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$
- Convert $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-1}$$
- Shift index using $k->k+1$
  $$u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$$
  Rewrite ODE with series expansions
  $$a_0r(-2+r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k+r-1) - a_k(k+r-1)\right)u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{0,2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\left(a_{k+1}(k+1+r)-a_k\right)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_k}{k+1+r}$

- Recursion relation for $r=0$

  $a_{k+1}=\frac{a_k}{k+1}$

- Solution for $r=0$

  $$\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+1}=\frac{a_k}{k+1}\right]$$

- Revert the change of variables $u=x-1$

  $$\left[y=\sum_{k=0}^{\infty} a_k(x-1)^k, a_{k+1}=\frac{a_k}{k+1}\right]$$

- Recursion relation for $r=2$

  $a_{k+1}=\frac{a_k}{k+3}$

- Solution for $r=2$

  $$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$$

- Revert the change of variables $u=x-1$

  $$\left[y=\sum_{k=0}^{\infty} a_k(x-1)^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$$

- Combine solutions and rename parameters

  $$\left[y=\left(\sum_{k=0}^{\infty} a_k(x-1)^k\right)+\left(\sum_{k=0}^{\infty} b_k(x-1)^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$$

1.43 problem 45

Internal problem ID [8181]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 45
Date solved : `Monday, October 21, 2024 at 04:54:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' - 4x(x+1)\,y' + (2x+3)\,y = 0$$

1.43.1 Solved as second order ode using Kovacic algorithm

Time used: 0.120 (sec)

Writing the ode as

$$4x^2y'' + \left(-4x^2 - 4x\right) y' + (2x+3)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x^2 - 4x \\ C &= 2x + 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 80: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x^2-4x}{4x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}+\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\,\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^2-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x+\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{x+\ln(x)}}{x}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\sqrt{x}\right) + c_2 \left(\sqrt{x}\left(\frac{e^{x+\ln(x)}}{x}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.43.2 Maple step by step solution

Let's solve
$4x^2\left(\frac{d}{dx}y'\right) - 4x(x+1)\,y' + (2x+3)\,y = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d}{dx}y'$
- Isolate 2nd derivative
  $\frac{d}{dx}y' = -\frac{(2x+3)y}{4x^2} + \frac{(x+1)y'}{x}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d}{dx}y' - \frac{(x+1)y'}{x} + \frac{(2x+3)y}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{x+1}{x}, P_3(x) = \frac{2x+3}{4x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -1$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = \frac{3}{4}$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$

- Multiply by denominators
  $4x^2\left(\frac{d}{dx}y'\right) - 4x(x+1)\,y' + (2x+3)\,y = 0$
- Assume series solution for y
  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

◦ Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

◦ Shift index using $k- >k + 1 - m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

◦ Convert $x^2 \cdot \left(\frac{d}{dx} y'\right)$ to series expansion

$$x^2 \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+2r)\,(-3+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r-1)\,(2k+2r-3) - 2a_{k-1}(2k+2r-3)\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$$(-1+2r)\,(-3+2r) = 0$$
- Values of r that satisfy the indicial equation
$$r \in \left\{\frac{1}{2}, \frac{3}{2}\right\}$$
- Each term in the series must be 0, giving the recursion relation
$$4\left(k+r-\frac{3}{2}\right)\left(\left(k+r-\frac{1}{2}\right) a_k - a_{k-1}\right) = 0$$
- Shift index using $k- >k + 1$
$$4\left(k+r-\frac{1}{2}\right)\left(\left(k+\frac{1}{2}+r\right) a_{k+1} - a_k\right) = 0$$
- Recursion relation that defines series solution to ODE
$$a_{k+1} = \frac{2a_k}{2k+1+2r}$$
- Recursion relation for $r = \frac{1}{2}$
$$a_{k+1} = \frac{2a_k}{2k+2}$$
- Solution for $r = \frac{1}{2}$
$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{2a_k}{2k+2}\right]$$
- Recursion relation for $r = \frac{3}{2}$

$a_{k+1} = \frac{2a_k}{2k+4}$

- Solution for $r = \frac{3}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+1} = \frac{2a_k}{2k+4}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+1} = \frac{2a_k}{2k+2}, b_{k+1} = \frac{2b_k}{2k+4}\right]$

1.44 problem 46

Internal problem ID [8182]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 46
Date solved : `Monday, October 21, 2024 at 04:54:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(3x-1)\,y''-(3x+2)\,y'-(6x-8)\,y=0$$

1.44.1 Solved as second order ode using Kovacic algorithm

Time used: 0.270 (sec)

Writing the ode as

$$(3x-1)\,y''+(-3x-2)\,y'+(-6x+8)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x-1 \\ B &= -3x-2 \\ C &= -6x+8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{81x^2 - 108x + 54}{4\left(3x - 1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 81x^2 - 108x + 54$$
$$t = 4(3x - 1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{81x^2 - 108x + 54}{4\left(3x - 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 82: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(3x-1)^2$. There is a pole at $x = \frac{1}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{4} + \frac{3}{4\left(x - \frac{1}{3}\right)^2} - \frac{3}{2\left(x - \frac{1}{3}\right)}$$

For the pole at $x = \frac{1}{3}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3}{2} - \frac{1}{2x} + \frac{1}{9x^3} + \frac{11}{108x^4} + \frac{7}{108x^5} + \frac{5}{162x^6} + \frac{2}{243x^7} - \frac{13}{3888x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{3}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{81x^2 - 108x + 54}{36x^2 - 24x + 4} \\ &= Q + \frac{R}{36x^2 - 24x + 4} \\ &= \left(\frac{9}{4}\right) + \left(\frac{-54x + 45}{36x^2 - 24x + 4}\right) \\ &= \frac{9}{4} + \frac{-54x + 45}{36x^2 - 24x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -54. Dividing this by leading coefficient in t which is 36 gives $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{3}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{3}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{3}{2}} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{81x^2 - 108x + 54}{4(3x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$\frac{1}{3}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{3}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(x - \frac{1}{3}\right)} + \left(\frac{3}{2}\right) \\
&= -\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2} \\
&= \frac{9x - 6}{6x - 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2}\right)(0) + \left(\left(\frac{1}{2\left(x - \frac{1}{3}\right)^2}\right) + \left(-\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2}\right)^2 - \left(\frac{81x^2 - 108x + 54}{4\left(3x - 1\right)^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2}\right) dx} \\
&= \frac{e^{\frac{3x}{2}}}{\sqrt{3x - 1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x-2}{3x-1}\,dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(3x-1)}{2}} \\
&= z_1\left(\sqrt{3x-1}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x-2}{3x-1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x+\ln(3x-1)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{x\,\mathrm{e}^{x+\ln(3x-1)}\mathrm{e}^{-4x}}{3x-1}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{2x}\right) + c_2\left(\mathrm{e}^{2x}\left(-\frac{x\,\mathrm{e}^{x+\ln(3x-1)}\mathrm{e}^{-4x}}{3x-1}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.44.2 Maple step by step solution

Let's solve

$(3x-1)\left(\frac{d}{dx}y'\right)-(3x+2)\,y'-(6x-8)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=\frac{2(3x-4)y}{3x-1}+\frac{(3x+2)y'}{3x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'-\frac{(3x+2)y'}{3x-1}-\frac{2(3x-4)y}{3x-1}=0$

□ Check to see if $x_0=\frac{1}{3}$ is a regular singular point

- ○ Define functions

$\left[P_2(x)=-\frac{3x+2}{3x-1}, P_3(x)=-\frac{2(3x-4)}{3x-1}\right]$

- ○ $\left(x-\frac{1}{3}\right)\cdot P_2(x)$ is analytic at $x=\frac{1}{3}$

$\left(\left(x-\frac{1}{3}\right)\cdot P_2(x)\right)\bigg|_{x=\frac{1}{3}}=-1$

- ○ $\left(x-\frac{1}{3}\right)^2\cdot P_3(x)$ is analytic at $x=\frac{1}{3}$

$\left(\left(x-\frac{1}{3}\right)^2\cdot P_3(x)\right)\bigg|_{x=\frac{1}{3}}=0$

- ○ $x=\frac{1}{3}$is a regular singular point

Check to see if $x_0=\frac{1}{3}$ is a regular singular point

$x_0=\frac{1}{3}$

- Multiply by denominators

$(3x-1)\left(\frac{d}{dx}y'\right)+(-3x-2)\,y'+(-6x+8)\,y=0$

- Change variables using $x=u+\frac{1}{3}$ so that the regular singular point is at $u=0$

$3u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-3u-3)\left(\frac{d}{du}y(u)\right)+(-6u+6)\,y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

$u^m\cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k->k-m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du} y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du} y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, u^{k+r}$

- Convert $u \cdot \left(\frac{d}{du} \frac{d}{du} y(u)\right)$ to series expansion

  $u \cdot \left(\frac{d}{du} \frac{d}{du} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, u^{k+r-1}$

- Shift index using $k->k+1$

  $u \cdot \left(\frac{d}{du} \frac{d}{du} y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $3a_0 r(-2+r)\, u^{-1+r} + \left(3a_1(1+r)\,(-1+r) - 3a_0(-2+r)\right) u^r + \left(\sum_{k=1}^{\infty} (3a_{k+1}(k+1+r)\,(k+r-\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $3r(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$
- Each term must be 0

  $3a_1(1+r)\,(-1+r) - 3a_0(-2+r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $3a_{k+1}(k+1+r)\,(k+r-1) + a_k(-3k-3r+6) - 6a_{k-1} = 0$
- Shift index using $k->k+1$

  $3a_{k+2}(k+2+r)\,(k+r) + a_{k+1}(-3k+3-3r) - 6a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{k a_{k+1} + r a_{k+1} + 2a_k - a_{k+1}}{(k+2+r)(k+r)}$
- Recursion relation for $r = 0$

  $a_{k+2} = \frac{k a_{k+1} + 2a_k - a_{k+1}}{(k+2)k}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = \frac{k a_{k+1} + 2a_k - a_{k+1}}{(k+2)k}$
- Recursion relation for $r = 2$

$a_{k+2} = \frac{k a_{k+1}+2 a_k+a_{k+1}}{(k+4)(k+2)}$

- Solution for $r = 2$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{k a_{k+1}+2 a_k+a_{k+1}}{(k+4)(k+2)}, 9a_1 = 0\right]$$

- Revert the change of variables $u = x - \frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x - \frac{1}{3}\right)^{k+2}, a_{k+2} = \frac{k a_{k+1}+2 a_k+a_{k+1}}{(k+4)(k+2)}, 9a_1 = 0\right]$$

1.45 problem 47

Internal problem ID [8183]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 47
Date solved : `Monday, October 21, 2024 at 04:54:59 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2+x)\,y''+xy'+3y=0$$

1.45.1 Solved as second order ode using Kovacic algorithm

Time used: 0.322 (sec)

Writing the ode as

$$(2+x)\,y''+xy'+3y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2+x\\ B&=x\\ C&=3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 12x - 20}{4\left(2 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 12x - 20$$
$$t = 4(2 + x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 12x - 20}{4\left(2 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 84: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2+x)^2$. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{(2+x)^2} - \frac{4}{2+x}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{4}{x} - \frac{6}{x^2} - \frac{72}{x^3} - \frac{556}{x^4} - \frac{5440}{x^5} - \frac{55088}{x^6} - \frac{586688}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 12x - 20}{4x^2 + 16x + 16} \\ &= Q + \frac{R}{4x^2 + 16x + 16} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-16x - 24}{4x^2 + 16x + 16}\right) \\ &= \frac{1}{4} + \frac{-16x - 24}{4x^2 + 16x + 16} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -16. Dividing this by leading coefficient in t which is 4 gives -4. Now b can be found.

$$\begin{aligned}b &= (-4) - (0)\\ &= -4\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2}\\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-4}{\frac{1}{2}} - 0\right) &&= -4\\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-4}{\frac{1}{2}} - 0\right) &&= 4\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 12x - 20}{4\,(2+x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-2	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	-4	4

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 4$ then

$$\begin{aligned}d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right)\\ &= 4 - (2)\\ &= 2\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{2}{2+x} + (-)\left(\frac{1}{2}\right) \\
&= \frac{2}{2+x} - \frac{1}{2} \\
&= -\frac{x-2}{2\,(2+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{2}{2+x} - \frac{1}{2}\right)(2x + a_1) + \left(\left(-\frac{2}{(2+x)^2}\right) + \left(\frac{2}{2+x} - \frac{1}{2}\right)^2 - \left(\frac{x^2 - 12x - 20}{4\,(2+x)^2}\right)\right) = 0$$

$$\frac{(a_1 + 6)\,x + 2a_0 + 2a_1 + 4}{2+x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 4, a_1 = -6\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 6x + 4$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \left(x^2 - 6x + 4\right) e^{\int \left(\frac{2}{2+x} - \frac{1}{2}\right) dx} \\
&= \left(x^2 - 6x + 4\right) e^{-\frac{x}{2} + 2\ln(2+x)} \\
&= \left(x^2 - 6x + 4\right) (2+x)^2\, e^{-\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{2+x}\,dx} \\
&= z_1 e^{-\frac{x}{2}+\ln(2+x)} \\
&= z_1\left((2+x)\,\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (2+x)^3\,\mathrm{e}^{-x}\left(x^2-6x+4\right)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{2+x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x+2\ln(2+x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{e}^{x}(x^4-x^3-18x^2-22x+8)}{240\,(x^2-6x+4)\,(2+x)^3}-\frac{\mathrm{e}^{-2}\,\mathrm{Ei}_1\left(-2-x\right)}{240}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((2+x)^3\,\mathrm{e}^{-x}\left(x^2-6x+4\right)\right) + c_2\Bigg((2+x)^3\,\mathrm{e}^{-x}\left(x^2-6x\right. \\
&\qquad \left.+4\right)\left(-\frac{\mathrm{e}^{x}(x^4-x^3-18x^2-22x+8)}{240\,(x^2-6x+4)\,(2+x)^3}-\frac{\mathrm{e}^{-2}\,\mathrm{Ei}_1\left(-2-x\right)}{240}\right)\Bigg)
\end{aligned}
$$

Will add steps showing solving for IC soon.

    $\left((2+x)\cdot P_2(x)\right)\Big|_{x=-2}=-2$

  ◦ $(2+x)^2\cdot P_3(x)$ is analytic at $x=-2$

    $\left((2+x)^2\cdot P_3(x)\right)\Big|_{x=-2}=0$

  ◦ $x=-2$is a regular singular point

  Check to see if $x_0=-2$ is a regular singular point

  $x_0=-2$

- Multiply by denominators

  $(2+x)\left(\frac{d}{dx}y'\right)+xy'+3y=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

  $u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(u-2)\left(\frac{d}{du}y(u)\right)+3y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-1}$$

- Shift index using $k->k+1$

$$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$a_0r(-3+r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k-2+r) + a_k(k+r+3)\right)u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-3+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 3\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(k-2+r) + a_k(k+r+3) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k(k+r+3)}{(k+1+r)(k-2+r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-2)}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 2$

$$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-2)}$$

- Recursion relation for $r = 3$

$$a_{k+1} = -\frac{a_k(k+6)}{(k+4)(k+1)}$$

- Solution for $r = 3$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+3}, a_{k+1} = -\frac{a_k(k+6)}{(k+4)(k+1)}\right]$$

- Revert the change of variables $u = 2 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k(2+x)^{k+3}, a_{k+1} = -\frac{a_k(k+6)}{(k+4)(k+1)}\right]$$

1.46 problem 48

Internal problem ID [8184]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 48
Date solved : `Monday, October 21, 2024 at 04:55:00 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-x)\,y''+x(4+x)\,y'+(2-x)\,y=0$$

1.46.1 Solved as second order ode using Kovacic algorithm

Time used: 0.244 (sec)

Writing the ode as

$$\left(-x^3+x^2\right)y''+\left(x^2+4x\right)y'+(2-x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^3+x^2\\B&=x^2+4x\\C&=2-x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-x + 36}{4x\left(-1 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -x + 36 \\
t &= 4x(-1 + x)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-x + 36}{4x\left(-1 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 86: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 3 - 1 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x(-1+x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{9}{-1+x} + \frac{35}{4\left(-1+x\right)^2} + \frac{9}{x}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x+36}{4x\left(-1+x\right)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{-x+36}{4x\left(-1+x\right)^{2}}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	1	0	0	1
1	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right)\\
&= \frac{1}{2}-\left(-\frac{3}{2}\right)\\
&= 2
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{x} - \frac{5}{2\left(-1+x\right)} + (-)\left(0\right) \\
&= \frac{1}{x} - \frac{5}{2\left(-1+x\right)} \\
&= \frac{1}{x} - \frac{5}{-2+2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x^2 + a_1 x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(2) + 2\left(\frac{1}{x} - \frac{5}{2\left(-1+x\right)}\right)\left(2x + a_1\right) + \left(\left(-\frac{1}{x^2} + \frac{5}{2\left(-1+x\right)^2}\right) + \left(\frac{1}{x} - \frac{5}{2\left(-1+x\right)}\right)^2 - \left(\frac{-x+36}{4x\left(-1+x\right)^2}\right.\right.
$$

$$
\frac{\left(a_1-6\right)x + 4a_0 - 2a_1}{x\left(-1+x\right)}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 3, a_1 = 6\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x^2 + 6x + 3
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 + 6x + 3\right) e^{\int \left(\frac{1}{x} - \frac{5}{2(-1+x)}\right) dx} \\
&= \left(x^2 + 6x + 3\right) e^{\ln(x) - \frac{5\ln(-1+x)}{2}} \\
&= \frac{\left(x^2 + 6x + 3\right) x}{\left(-1+x\right)^{5/2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+4x}{-x^3+x^2}\,dx} \\
&= z_1 e^{-2\ln(x)+\frac{5\ln(-1+x)}{2}} \\
&= z_1\left(\frac{(-1+x)^{5/2}}{x^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^2+6x+3}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+4x}{-x^3+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4\ln(x)+5\ln(-1+x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{4\left(-38x-\frac{69}{2}\right)}{9\left(x^2+6x+3\right)}+\ln\left(x\right)+\frac{1}{9x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^2+6x+3}{x}\right) + c_2\left(\frac{x^2+6x+3}{x}\left(-\frac{4\left(-38x-\frac{69}{2}\right)}{9\left(x^2+6x+3\right)}+\ln\left(x\right)+\frac{1}{9x}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.47 problem 49

Internal problem ID [8185]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 49
Date solved : `Monday, October 21, 2024 at 04:55:01 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''+x(1+2x)\,y'-(4+6x)\,y=0$$

1.47.1 Solved as second order ode using Kovacic algorithm

Time used: 0.254 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(2x^2+x\right)y'+(-6x-4)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(1+x) \\ B &= 2x^2+x \\ C &= -6x-4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{24x^2 + 40x + 15}{4\left(x^2 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 24x^2 + 40x + 15$$
$$t = 4\left(x^2 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{24x^2 + 40x + 15}{4\left(x^2 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 87: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{5}{2x} - \frac{5}{2(1+x)} + \frac{15}{4x^2} - \frac{1}{4(1+x)^2}
$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{24x^2 + 40x + 15}{4(x^2 + x)^2}
$$

Since the gcd$(s,t)=1$. This gives $b=6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=3 \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-2
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{24x^2+40x+15}{4\left(x^2+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=3$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+}-\left(\alpha_{c_1}^{+}+\alpha_{c_2}^{+}\right) \\
&= 3-(3) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2 + 2x} + \frac{5}{2x} + (0) \\
&= \frac{1}{2 + 2x} + \frac{5}{2x} \\
&= \frac{6x + 5}{2x\,(1 + x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{1}{2 + 2x} + \frac{5}{2x}\right)(0) + \left(\left(-\frac{1}{2\,(1 + x)^2} - \frac{5}{2x^2}\right) + \left(\frac{1}{2 + 2x} + \frac{5}{2x}\right)^2 - \left(\frac{24x^2 + 40x + 15}{4\,(x^2 + x)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2+2x} + \frac{5}{2x}\right) dx} \\
&= \sqrt{1 + x}\, x^{5/2}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2x^2 + x}{x^2 (1+x)} \, dx} \\
&= z_1 e^{-\frac{\ln(x(1+x))}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x\,(1 + x)}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{\sqrt{1+x}\, x^{5/2}}{\sqrt{x\,(1+x)}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2+x}{x^2(1+x)}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x(1+x))}}{(y_1)^2}\, dx \\
&= y_1 \left(-\ln(1+x) - \frac{1}{4x^4} - \frac{1}{2x^2} + \ln(x) + \frac{1}{3x^3} + \frac{1}{x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{1+x}\, x^{5/2}}{\sqrt{x\,(1+x)}}\right) + c_2 \left(\frac{\sqrt{1+x}\, x^{5/2}}{\sqrt{x\,(1+x)}} \left(-\ln(1+x) - \frac{1}{4x^4} - \frac{1}{2x^2} + \ln(x) + \frac{1}{3x^3} + \frac{1}{x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.47.2 Maple step by step solution

Let's solve

$x^2(1+x)\left(\frac{d}{dx}y'\right) + x(1+2x)\,y' - (4+6x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{2(2+3x)y}{x^2(1+x)} - \frac{(1+2x)y'}{x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y' + \frac{(1+2x)y'}{x(1+x)} - \frac{2(2+3x)y}{x^2(1+x)} = 0$

- □ Check to see if x_0 is a regular singular point
  - ○ Define functions

    $\left[P_2(x) = \frac{1+2x}{x(1+x)}, P_3(x) = -\frac{2(2+3x)}{x^2(1+x)}\right]$
  - ○ $(1+x) \cdot P_2(x)$ is analytic at $x = -1$

    $$\left((1+x) \cdot P_2(x)\right)\Bigg|_{x=-1} = 1$$
  - ○ $(1+x)^2 \cdot P_3(x)$ is analytic at $x = -1$

    $$\left((1+x)^2 \cdot P_3(x)\right)\Bigg|_{x=-1} = 0$$
  - ○ $x = -1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -1$
- • Multiply by denominators

  $x^2(1+x)\left(\frac{d}{dx}y'\right) + x(1+2x)\,y' + (-6x-4)\,y = 0$
- • Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^3 - 2u^2 + u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (2u^2 - 3u + 1)\left(\frac{d}{du}y(u)\right) + (-6u + 2)\,y(u) = 0$
- • Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$
- □ Rewrite ODE with series expansions
  - ○ Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

    $$u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$$
  - ○ Shift index using $k- >k - m$

    $$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$
  - ○ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

    $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$$
  - ○ Shift index using $k- >k + 1 - m$

    $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$
  - ○ Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r^2 u^{-1+r} + \left(a_1(1+r)^2 - a_0(2r^2+r-2)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)^2 - a_k(2k^2+4kr+2r^2+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 0$$

- Each term must be 0

$$a_1(1+r)^2 - a_0(2r^2+r-2) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2-k-6)\, a_{k-1} + (-2k^2-k+2)\, a_k + a_{k+1}(k+1)^2 = 0$$

- Shift index using $k->k+1$

$$\left((k+1)^2-k-7\right) a_k + \left(-2(k+1)^2-k+1\right) a_{k+1} + a_{k+2}(k+2)^2 = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}, a_1 + 2a_0 = 0\right]$$

- Revert the change of variables $u = 1+x$

$$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}, a_1 + 2a_0 = 0\right]$$

1.48 problem 50

Internal problem ID [8186]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 50
Date solved : `Monday, October 21, 2024 at 04:55:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(2x^2+1\right)y''+x\left(2x^2+4\right)y'+2\left(-x^2+1\right)y=0$$

1.48.1 Solved as second order ode using Kovacic algorithm

Time used: 0.373 (sec)

Writing the ode as

$$\left(2x^4+x^2\right)y''+\left(2x^3+4x\right)y'+\left(-2x^2+2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+x^2 \\ B &= 2x^3+4x \\ C &= -2x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{3x^2 - 9}{(2x^2 + 1)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 3x^2 - 9 \\
t &= (2x^2 + 1)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{3x^2 - 9}{(2x^2 + 1)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A} dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 89: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2+1)^2$. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{21}{16\left(x - \frac{i\sqrt{2}}{2}\right)^2} + \frac{21}{16\left(x + \frac{i\sqrt{2}}{2}\right)^2} + \frac{15i\sqrt{2}}{16\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{15i\sqrt{2}}{16\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 - 9}{\left(2x^2 + 1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x^2 - 9}{\left(2x^2 + 1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{3}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{4\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{3}{4\left(x + \frac{i\sqrt{2}}{2}\right)} + (-)(0) \\
&= -\frac{3}{4\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{3}{4\left(x + \frac{i\sqrt{2}}{2}\right)} \\
&= -\frac{3x}{2x^2 + 1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{4\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{3}{4\left(x + \frac{i\sqrt{2}}{2}\right)} \right)(1) + \left(\left(\frac{3}{4\left(x - \frac{i\sqrt{2}}{2}\right)^2} + \frac{3}{4\left(x + \frac{i\sqrt{2}}{2}\right)^2} \right) + \left(-\frac{3}{4\left(x - \frac{i\sqrt{2}}{2}\right)} - \right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= (x)\, \mathrm{e}^{\int \left(-\frac{3}{4\left(x-\frac{i\sqrt{2}}{2}\right)}-\frac{3}{4\left(x+\frac{i\sqrt{2}}{2}\right)}\right)dx} \\
&= (x)\, \frac{1}{\left(\left(i\sqrt{2}-2x\right)\left(2x+i\sqrt{2}\right)\right)^{3/4}} \\
&= \frac{x}{\left(-4x^2-2\right)^{3/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3+4x}{2x^4+x^2}\, dx} \\
&= z_1 e^{-2\ln(x)+\frac{3\ln\left(2x^2+1\right)}{4}} \\
&= z_1 \left(\frac{\left(2x^2+1\right)^{3/4}}{x^2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{2^{1/4}\left(4x^2+2\right)^{3/4}}{2x\left(-4x^2-2\right)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+4x}{2x^4+x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-4\ln(x)+\frac{3\ln\left(2x^2+1\right)}{2}}}{\left(y_1\right)^2}\, dx
\end{aligned}$$

$$
= y_1 \left(-\frac{2i(2x^4 - x^2 - 1)\sqrt{2x^2+1}\,\sqrt{2}\,\sqrt{\frac{(-4x^2-2)(4x^2+2)}{(2x^2+1)^2}}}{x\sqrt{-4x^2-2}\,\sqrt{4x^2+2}} - \frac{6i\,\mathrm{arcsinh}\left(\sqrt{2}\,x\right)\sqrt{\frac{(-4x^2-2)(4x^2+2)}{(2x^2+1)^2}}\,(2x^2+1)}{\sqrt{-4x^2-2}\,\sqrt{4x^2+2}} \right)
$$

Therefore the solution is

$$
y = c_1 y_1 + c_2 y_2
$$

$$
= c_1 \left(\frac{2^{1/4}(4x^2+2)^{3/4}}{2x\left(-4x^2-2\right)^{3/4}} \right) + c_2 \left(\frac{2^{1/4}(4x^2+2)^{3/4}}{2x\left(-4x^2-2\right)^{3/4}} \left(-\frac{2i(2x^4 - x^2 - 1)\sqrt{2x^2+1}\,\sqrt{2}\,\sqrt{\frac{(-4x^2-2)(4x^2+2)}{(2x^2+1)^2}}}{x\sqrt{-4x^2-2}\,\sqrt{4x^2+2}} - \frac{6i
$$

Will add steps showing solving for IC soon.

1.48.2 Maple step by step solution

Let's solve

$x^2(2x^2+1)\left(\frac{d}{dx}y'\right) + x(2x^2+4)\,y' + 2(-x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{2(x^2-1)y}{x^2(2x^2+1)} - \frac{2(x^2+2)y'}{x(2x^2+1)}$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2+2)\,y''+2x(x^2+5)\,y'+2(-x^2+3)\,y=0$$

1.49.1 Solved as second order ode using Kovacic algorithm

Time used: 0.508 (sec)

Writing the ode as

$$\left(x^4+2x^2\right)y''+\left(2x^3+10x\right)y'+\left(-2x^2+6\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+2x^2\\ B &= 2x^3+10x\\ C &= -2x^2+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2x^4 - 5x^2 + 3}{(x^3 + 2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2x^4 - 5x^2 + 3$$
$$t = (x^3 + 2x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2x^4 - 5x^2 + 3}{(x^3 + 2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 91: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = \left(x^3 + 2x\right)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2} + \frac{21}{16\left(x - i\sqrt{2}\right)^2} + \frac{21}{16\left(x + i\sqrt{2}\right)^2} + \frac{11i\sqrt{2}}{32\left(x - i\sqrt{2}\right)} - \frac{11i\sqrt{2}}{32\left(x + i\sqrt{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x=-i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{21}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{7}{4}\\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=-\frac{3}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r=\frac{s}{t}=\frac{2x^4-5x^2+3}{(x^3+2x)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=2\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{2x^4-5x^2+3}{(x^3+2x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$i\sqrt{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$-i\sqrt{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= 2 - (0) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{3}{2x} - \frac{3}{4\left(x-i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)} + (0) \\ &= \frac{3}{2x} - \frac{3}{4\left(x-i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)} \\ &= \frac{3}{x^3+2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{3}{2x} - \frac{3}{4\left(x-i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)}\right)(2x+a_1) + \left(\left(-\frac{3}{2x^2} + \frac{3}{4\left(x-i\sqrt{2}\right)^2} + \frac{3}{4\left(x+i\sqrt{2}\right)^2}\right) + \right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 8, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 8$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2+8\right) \mathrm{e}^{\int \left(\frac{3}{2x} - \frac{3}{4\left(x - i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)}\right) dx} \\
&= \left(x^2+8\right) \mathrm{e}^{-\frac{3\ln\left(x^2+2\right)}{4} + \frac{3\ln(x)}{2}} \\
&= \frac{\left(x^2+8\right) x^{3/2}}{\left(x^2+2\right)^{3/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2x^3+10x}{x^4+2x^2} \, dx} \\
&= z_1 e^{\frac{3\ln\left(x^2+2\right)}{4} - \frac{5\ln(x)}{2}} \\
&= z_1 \left(\frac{\left(x^2+2\right)^{3/4}}{x^{5/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2+8}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+10x}{x^4+2x^2} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{3\ln\left(x^2+2\right)}{2} - 5\ln(x)}}{\left(y_1\right)^2} \, dx
\end{aligned}$$

$$= y_1 \left(-\frac{(x^2+2)^{5/2}}{256x^2} + \frac{(x^2+2)^{3/2}}{384} + \frac{\sqrt{x^2+2}}{96} - \frac{\sqrt{2}\,\mathrm{arctanh}\left(\frac{\sqrt{2}}{\sqrt{x^2+2}}\right)}{64} + \frac{3\sqrt{x^2+2}}{64\,(x^2+8)} + \frac{x^2\sqrt{x^2+2}}{768} \right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x^2+8}{x} \right) + c_2 \left(\frac{x^2+8}{x} \left(-\frac{(x^2+2)^{5/2}}{256x^2} + \frac{(x^2+2)^{3/2}}{384} + \frac{\sqrt{x^2+2}}{96} - \frac{\sqrt{2}\,\mathrm{arctanh}\left(\frac{\sqrt{2}}{\sqrt{x^2+2}}\right)}{64} + \frac{3\sqrt{x^2+2}}{64\,(x^2+8)} + \frac{x^2\sqrt{x^2+2}}{768} \right) \right)$$

Will add steps showing solving for IC soon.

1.49.2 Maple step by step solution

Let's solve

$x^2(x^2+2)\left(\frac{d}{dx}y'\right) + 2x(x^2+5)\,y' + 2(-x^2+3)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{2(x^2-3)y}{x^2(x^2+2)} - \frac{2(x^2+5)y'}{x(x^2+2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{2(x^2+5)y'}{x(x^2+2)} - \frac{2(x^2-3)y}{x^2(x^2+2)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{2(x^2+5)}{x(x^2+2)}, P_3(x) = -\frac{2(x^2-3)}{x^2(x^2+2)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = 5$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 3$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$x^2(x^2+2)\left(\frac{d}{dx}y'\right) + 2x(x^2+5)\,y' + (-2x^2+6)\,y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- Shift index using $k- >k + 2 - m$

  $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$2a_0(3+r)\,(1+r)\,x^r + 2a_1(4+r)\,(2+r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} \left(2a_k(k+r+3)\,(k+r+1) + a_{k-2}(k+r)\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $2(3+r)\,(1+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{-3, -1\}$

- Each term must be 0

  $2a_1(4+r)(2+r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $2a_k(k+r+3)(k+r+1) + a_{k-2}(k+r)(k-3+r) = 0$
- Shift index using $k- >k+2$

  $2a_{k+2}(k+5+r)(k+r+3) + a_k(k+r+2)(k+r-1) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+2)(k+r-1)}{2(k+5+r)(k+r+3)}$
- Recursion relation for $r = -3$; series terminates at $k = 4$

  $a_{k+2} = -\frac{a_k(k-1)(k-4)}{2(k+2)k}$
- Solution for $r = -3$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-3}, a_{k+2} = -\frac{a_k(k-1)(k-4)}{2(k+2)k}, a_1 = 0\right]$
- Recursion relation for $r = -1$; series terminates at $k = 2$

  $a_{k+2} = -\frac{a_k(k+1)(k-2)}{2(k+4)(k+2)}$
- Solution for $r = -1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{a_k(k+1)(k-2)}{2(k+4)(k+2)}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-3}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), a_{k+2} = -\frac{a_k(k-1)(k-4)}{2(k+2)k}, a_1 = 0, b_{k+2} = -\frac{b_k(k+1)(k-2)}{2(k+4)(k+2)}, b_1 = 0\right]$

1.50 problem 52

Internal problem ID [8188]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 52
Date solved : `Monday, October 21, 2024 at 04:55:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right)y''+6xy'+6y=0$$

1.50.1 Solved as second order ode using Kovacic algorithm

Time used: 0.283 (sec)

Writing the ode as

$$\left(x^2+1\right)y''+6xy'+6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= 6x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{3}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 93: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 0\\ &= 4\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} + \frac{3i}{4(x-i)} - \frac{3i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{3}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(x-i)} + \frac{3}{2(x+i)} + (-)(0) \\
&= -\frac{1}{2(x-i)} + \frac{3}{2(x+i)} \\
&= \frac{x-2i}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(x-i)} + \frac{3}{2(x+i)}\right)(0) + \left(\left(\frac{1}{2(x-i)^2} - \frac{3}{2(x+i)^2}\right) + \left(-\frac{1}{2(x-i)} + \frac{3}{2(x+i)}\right)^2 - \left(-\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-i)} + \frac{3}{2(x+i)}\right) dx} \\
&= \frac{\left(x^2+1\right)^{3/2}}{\left(ix+1\right)^2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{6x}{x^2+1} \, dx} \\
&= z_1 e^{-\frac{3 \ln\left(x^2+1\right)}{2}} \\
&= z_1 \left(\frac{1}{\left(x^2+1\right)^{3/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{\left(ix+1\right)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6x}{x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3\ln(x^2+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{x}{(x+i)^2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{(ix+1)^2}\right) + c_2 \left(\frac{1}{(ix+1)^2}\left(-\frac{x}{(x+i)^2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.51 problem 53

Internal problem ID [8189]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 53
Date solved : `Monday, October 21, 2024 at 04:55:05 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''+2xy'-2y=0$$

1.51.1 Solved as second order ode using Kovacic algorithm

Time used: 0.287 (sec)

Writing the ode as

$$\left(x^2+1\right) y''+2xy'-2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= 2x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2x^2 + 3}{(x^2 + 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2x^2 + 3$$
$$t = (x^2 + 1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2x^2 + 3}{(x^2 + 1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 94: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-i)^2} - \frac{1}{4(x+i)^2} - \frac{5i}{4(x-i)} + \frac{5i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^2+3}{(x^2+1)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=2 \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{2x^2+3}{(x^2+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
i	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-i$	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=2$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right) \\
&= 2-(1) \\
&= 1
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} + (0) \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} \\
&= \frac{x}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)(1) + \left(\left(-\frac{1}{2(x-i)^2} - \frac{1}{2(x+i)^2}\right) + \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)^2 - \left(\frac{2x^2+3}{(x^2+1)^2}\right.\right.
$$

$$
-\frac{2(x^2+1)\,a_0}{(-x+i)^2\,(x+i)^2}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x)\, e^{\int \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right) dx} \\
&= (x)\sqrt{(-x+i)(x+i)} \\
&= x\sqrt{-x^2-1}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2+1}\,dx} \\
&= z_1 e^{-\frac{\ln\left(x^2+1\right)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x^2+1}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = ix
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2+1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x^2+1)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\frac{1}{x} + \arctan\left(x\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(ix) + c_2\left(ix\left(\frac{1}{x} + \arctan\left(x\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.52 problem 54

Internal problem ID [8190]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 54
Date solved : `Monday, October 21, 2024 at 04:55:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y'' - 8xy' + 20y = 0$$

1.52.1 Solved as second order ode using Kovacic algorithm

Time used: 0.316 (sec)

Writing the ode as

$$\left(x^2+1\right) y'' - 8xy' + 20y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -8x \\ C &= 20 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-24}{(x^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -24$$
$$t = (x^2+1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{24}{(x^2+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 95: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 + 1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{(x-i)^2} + \frac{6}{(x+i)^2} + \frac{6i}{x-i} - \frac{6i}{x+i}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{24}{\left(x^2+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	3	-2
$-i$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{2}{x-i} + \frac{3}{x+i} + (-)(0) \\ &= -\frac{2}{x-i} + \frac{3}{x+i} \\ &= \frac{x-5i}{x^2+1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{2}{x-i} + \frac{3}{x+i}\right)(0) + \left(\left(\frac{2}{(x-i)^2} - \frac{3}{(x+i)^2}\right) + \left(-\frac{2}{x-i} + \frac{3}{x+i}\right)^2 - \left(-\frac{24}{(x^2+1)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{2}{x-i} + \frac{3}{x+i}\right) dx} \\
&= \frac{(x^2+1)^3}{(ix+1)^5}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-8x}{x^2+1} \, dx} \\
&= z_1 e^{2\ln(x^2+1)} \\
&= z_1\left(\left(x^2+1\right)^2\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2+1)^5}{(ix+1)^5}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{-8x}{x^2+1}\,dx}}{(y_1)^2}\,dx$$
$$= y_1 \int \frac{e^{4\ln(x^2+1)}}{(y_1)^2}\,dx$$
$$= y_1 \left(\frac{x^4 - 2x^2 + \frac{1}{5}}{(x+i)^5}\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{(x^2+1)^5}{(ix+1)^5}\right) + c_2 \left(\frac{(x^2+1)^5}{(ix+1)^5} \left(\frac{x^4 - 2x^2 + \frac{1}{5}}{(x+i)^5}\right)\right)$$

Will add steps showing solving for IC soon.

1.53 problem 55

Internal problem ID [8191]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 55
Date solved : `Monday, October 21, 2024 at 04:55:07 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-x^2+1\right) y''-8xy'-12y=0$$

1.53.1 Solved as second order ode using Kovacic algorithm

Time used: 0.266 (sec)

Writing the ode as

$$\left(-x^2+1\right) y''-8xy'-12y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^2+1 \\ B &= -8x \\ C &= -12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \\ = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{8}{(x^2-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 8$$
$$t = (x^2-1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{8}{(x^2-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 96: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x+1} - \frac{2}{x-1} + \frac{2}{(x+1)^2} + \frac{2}{(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{8}{(x^2-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	2	-1
-1	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x-1} + \frac{2}{x+1} + (-)\,(0) \\
&= -\frac{1}{x-1} + \frac{2}{x+1} \\
&= \frac{x-3}{x^2-1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x-1} + \frac{2}{x+1}\right)(0) + \left(\left(\frac{1}{(x-1)^2} - \frac{2}{(x+1)^2}\right) + \left(-\frac{1}{x-1} + \frac{2}{x+1}\right)^2 - \left(\frac{8}{(x^2-1)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(-\frac{1}{x-1} + \frac{2}{x+1}\right) dx} \\ &= \frac{(x+1)^2}{x-1} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-8x}{-x^2+1}\, dx} \\ &= z_1 e^{-2\ln(x-1) - 2\ln(x+1)} \\ &= z_1 \left(\frac{1}{(x-1)^2 (x+1)^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{(x-1)^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-8x}{-x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4\ln(x-1)-4\ln(x+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{(x+1)\,(3x^2+1)\,(x-1)^4\,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{(x-1)^3}\right) + c_2 \left(\frac{1}{(x-1)^3} \left(-\frac{(x+1)\,(3x^2+1)\,(x-1)^4\,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.53.2 Maple step by step solution

Let's solve

$(-x^2+1)\left(\frac{d}{dx}y'\right) - 8xy' - 12y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{12y}{x^2-1} - \frac{8xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{8xy'}{x^2-1} + \frac{12y}{x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{8x}{x^2-1}, P_3(x) = \frac{12}{x^2-1}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = 4$

- $(x+1)^2 \cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$
- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d}{dx}y'\right) + 8xy' + 12y = 0$
- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (8u-8)\left(\frac{d}{du}y(u)\right) + 12y(u) = 0$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$
- Shift index using $k- >k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$
- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$
- Shift index using $k- >k+2-m$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0 r(3+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)(k+r+4) + a_k(k+r+4)(k+r+3)\right) u^{k+r}\right) =$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-3, 0\}$
- Each term in the series must be 0, giving the recursion relation

  $(k+r+4)\left((-2k-2r-2)\, a_{k+1} + a_k(k+r+3)\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r+3)}{2(k+1+r)}$
- Recursion relation for $r = -3$

  $a_{k+1} = \frac{a_k k}{2(k-2)}$
- Series not valid for $r = -3$, division by 0 in the recursion relation at $k = 2$

  $a_{k+1} = \frac{a_k k}{2(k-2)}$
- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k(k+3)}{2(k+1)}$
- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k+3)}{2(k+1)}\right]$
- Revert the change of variables $u = x + 1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x+1)^k, a_{k+1} = \frac{a_k(k+3)}{2(k+1)}\right]$

1.54 problem 56

Internal problem ID [8192]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 56
Date solved : `Monday, October 21, 2024 at 04:55:08 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2+1\right)y''+7xy'+2y=0$$

1.54.1 Solved as second order ode using Kovacic algorithm

Time used: 0.434 (sec)

Writing the ode as

$$\left(2x^2+1\right)y''+7xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^2+1\\ B&=7x\\ C&=2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5x^2 + 6}{4\left(2x^2 + 1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 5x^2 + 6$$
$$t = 4\left(2x^2 + 1\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5x^2 + 6}{4\left(2x^2 + 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 98: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2+1)^2$. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{7}{64\left(x + \frac{i\sqrt{2}}{2}\right)^2} - \frac{17i\sqrt{2}}{64\left(x - \frac{i\sqrt{2}}{2}\right)} + \frac{17i\sqrt{2}}{64\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5x^2+6}{4\left(2x^2+1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{5x^2+6}{4\left(2x^2+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{5}{4} - \left(\frac{1}{4}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}} + (0) \\
&= \frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}} \\
&= \frac{x}{4x^2 + 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}}\right)(1) + \left(\left(-\frac{1}{8\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{1}{8\left(x + \frac{i\sqrt{2}}{2}\right)^2}\right) + \left(\frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4}\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x) \, e^{\int \left(\frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}}\right) dx} \\
&= (x) \left(\left(i\sqrt{2} - 2x\right) \left(2x + i\sqrt{2}\right) \right)^{1/8} \\
&= x \left(-4x^2 - 2\right)^{1/8}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x}{2x^2+1}\,dx} \\
&= z_1 e^{-\frac{7\ln\left(2x^2+1\right)}{8}} \\
&= z_1 \left(\frac{1}{\left(2x^2+1\right)^{7/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{2^{7/8} x(-4x^2-2)^{1/8}}{\left(4x^2+2\right)^{7/8}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x}{2x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{7\ln\left(2x^2+1\right)}{4}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{2^{1/4}(4x^2+2)^{7/4}}{4\left(2x^2+1\right)^{7/4} x^2 \left(-4x^2-2\right)^{1/4}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{2^{7/8} x(-4x^2-2)^{1/8}}{\left(4x^2+2\right)^{7/8}}\right) + c_2 \left(\frac{2^{7/8} x(-4x^2-2)^{1/8}}{\left(4x^2+2\right)^{7/8}}\left(\int \frac{2^{1/4}(4x^2+2)^{7/4}}{4\left(2x^2+1\right)^{7/4} x^2 \left(-4x^2-2\right)^{1/4}}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.55 problem 57

Internal problem ID [8193]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 57
Date solved : `Monday, October 21, 2024 at 04:55:09 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-x^2+1\right) y''-5 x y'-4 y=0$$

1.55.1 Solved as second order ode using Kovacic algorithm

Time used: 0.277 (sec)

Writing the ode as

$$\left(-x^2+1\right) y''-5 x y'-4 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^2+1 \\ B &= -5x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-x^2 + 6}{4\left(x^2 - 1\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -x^2 + 6 \\
t &= 4\left(x^2 - 1\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-x^2 + 6}{4\left(x^2 - 1\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 99: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{16(x-1)} + \frac{5}{16(x+1)^2} + \frac{7}{16(x+1)} + \frac{5}{16(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2+6}{4(x^2-1)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-x^2+6}{4\left(x^2-1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
-1	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right) \\
&= \frac{1}{2}-\left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)} + (-)\left(0\right) \\
&= -\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)} \\
&= -\frac{x}{2x^{2}-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^{2} - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)}\right)(1) + \left(\left(\frac{1}{4\left(x-1\right)^{2}} + \frac{1}{4\left(x+1\right)^{2}}\right) + \left(-\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)}\right)^{2} - \Big(
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x\right) \mathrm{e}^{\int \left(-\frac{1}{4(x-1)} - \frac{1}{4(x+1)}\right) dx} \\
&= \left(x\right) \frac{1}{\left(\left(x-1\right)\left(x+1\right)\right)^{1/4}} \\
&= \frac{x}{\left(x^{2}-1\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5x}{-x^2+1}\,dx} \\
&= z_1 e^{-\frac{5\ln(x-1)}{4}-\frac{5\ln(x+1)}{4}} \\
&= z_1 \left(\frac{1}{(x-1)^{5/4}(x+1)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x}{(x-1)^{5/4}(x+1)^{5/4}(x^2-1)^{1/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5x}{-x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{5\ln(x-1)}{2}-\frac{5\ln(x+1)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{(x^2-1)^{3/2}}{x} - x\sqrt{x^2-1} + \ln\left(x+\sqrt{x^2-1}\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x}{(x-1)^{5/4}(x+1)^{5/4}(x^2-1)^{1/4}}\right) + c_2 \left(\frac{x}{(x-1)^{5/4}(x+1)^{5/4}(x^2-1)^{1/4}}\left(\frac{(x^2-1)^{3/2}}{x} - x\sqrt{x^2-1} +
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.55.2 Maple step by step solution

Let's solve

$(-x^2+1)\left(\frac{d}{dx}y'\right)-5xy'-4y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{4y}{x^2-1}-\frac{5xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{5xy'}{x^2-1}+\frac{4y}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{5x}{x^2-1}, P_3(x)=\frac{4}{x^2-1}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\bigg|_{x=-1}=\frac{5}{2}$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\bigg|_{x=-1}=0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d}{dx}y'\right)+5xy'+4y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(5u-5)\left(\frac{d}{du}y(u)\right)+4y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0r(3+2r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(2k+5+2r) + a_k(k+r+2)^2\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(3+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{3}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r+2)^2 - 2\left(k+\frac{5}{2}+r\right) a_{k+1}(k+1+r) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k(k+r+2)^2}{(2k+5+2r)(k+1+r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{a_k(k+2)^2}{(2k+5)(k+1)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k+2)^2}{(2k+5)(k+1)}\right]$$

- Revert the change of variables $u = x+1$

$$\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+1} = \frac{a_k(k+2)^2}{(2k+5)(k+1)}\right]$$

- Recursion relation for $r = -\frac{3}{2}$

$$a_{k+1} = \frac{a_k\left(k+\frac{1}{2}\right)^2}{(2k+2)\left(k-\frac{1}{2}\right)}$$

- Solution for $r = -\frac{3}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{3}{2}}, a_{k+1} = \frac{a_k\left(k+\frac{1}{2}\right)^2}{(2k+2)\left(k-\frac{1}{2}\right)}\right]$$

- Revert the change of variables $u = x+1$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+1)^{k-\frac{3}{2}}, a_{k+1} = \frac{a_k \left(k+\frac{1}{2}\right)^2}{(2k+2)\left(k-\frac{1}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (x+1)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x+1)^{k-\frac{3}{2}}\right), a_{k+1} = \frac{a_k (k+2)^2}{(2k+5)(k+1)}, b_{k+1} = \frac{b_k \left(k+\frac{1}{2}\right)^2}{(2k+2)\left(k-\frac{1}{2}\right)}\right]$$

1.56 problem 58

Internal problem ID [8194]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 58
Date solved : `Monday, October 21, 2024 at 04:55:10 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''-10 x y'+28 y=0$$

1.56.1 Solved as second order ode using Kovacic algorithm

Time used: 0.366 (sec)

Writing the ode as

$$\left(x^2+1\right) y''-10 x y'+28 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -10 x \\ C &= 28 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{2x^2 - 33}{(x^2 + 1)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 2x^2 - 33 \\
t &= (x^2 + 1)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{2x^2 - 33}{(x^2 + 1)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 101: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4(x-i)^2} + \frac{35}{4(x+i)^2} + \frac{31i}{4(x-i)} - \frac{31i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^2 - 33}{(x^2+1)^2}$$

Since the gcd$(s,t)=1$. This gives $b=2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=2 \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{2x^2-33}{(x^2+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
i	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
$-i$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=2$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right) \\
&= 2-(1) \\
&= 1
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= -\frac{5}{2\left(x - i\right)} + \frac{7}{2\left(x + i\right)} + (0) \\
&= -\frac{5}{2\left(x - i\right)} + \frac{7}{2\left(x + i\right)} \\
&= \frac{x - 6i}{x^2 + 1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{5}{2\left(x - i\right)} + \frac{7}{2\left(x + i\right)}\right)(1) + \left(\left(\frac{5}{2\left(x - i\right)^2} - \frac{7}{2\left(x + i\right)^2}\right) + \left(-\frac{5}{2\left(x - i\right)} + \frac{7}{2\left(x + i\right)}\right)^2 - \left(\frac{2x^{\cdots}}{(x^{2\cdots}}\right.\right.
$$

$$
-\frac{2(x^2 + 1)\left(6i \cdots\right.}{\left(-x + i\right)^2 \left(x \cdots\right.}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = -6i\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x - 6i
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x - 6i\right) e^{\int \left(-\frac{5}{2(x-i)} + \frac{7}{2(x+i)}\right) dx} \\
&= \left(x - 6i\right) e^{\frac{\ln\left(x^2+1\right)}{2} - 6i \arctan(x)} \\
&= \frac{\left(-x + 6i\right)\left(x^2 + 1\right)^{7/2}}{\left(-x + i\right)^6}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-10x}{x^2+1}\,dx} \\
&= z_1 e^{\frac{5\ln\left(x^2+1\right)}{2}} \\
&= z_1\left(\left(x^2+1\right)^{5/2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(x^2+1\right)^6 (-x+6i)}{(-x+i)^6}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-10x}{x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{5\ln(x^2+1)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{3125}{823543\,(x-6i)} + \frac{724i}{2401\,(x+i)^4} - \frac{16i}{147\,(x+i)^6} - \frac{3125i}{117649\,(x+i)^2} \right. \\
&\quad \left. + \frac{496}{1715\,(x+i)^5} - \frac{7432}{50421\,(x+i)^3} - \frac{3125}{823543\,(x+i)}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\left(x^2+1\right)^6 (-x+6i)}{(-x+i)^6}\right) + c_2\left(\frac{\left(x^2+1\right)^6 (-x+6i)}{(-x+i)^6}\left(\frac{3125}{823543\,(x-6i)} + \frac{724i}{2401\,(x+i)^4} \right.\right. \\
&\quad - \frac{16i}{147\,(x+i)^6} - \frac{3125i}{117649\,(x+i)^2} + \frac{496}{1715\,(x+i)^5} - \frac{7432}{50421\,(x+i)^3} \\
&\quad \left.\left. - \frac{3125}{823543\,(x+i)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Solve

$$y'' + xy' + 2y = 0$$

1.57.1 Solved as second order ode using Kovacic algorithm

Time used: 0.257 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 6$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 102: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 6}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{3}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= -2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) &= 0 \\ a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega \, dx} \\ &= (x)\, \mathrm{e}^{\int -\frac{x}{2} dx} \\ &= (x)\, \mathrm{e}^{-\frac{x^2}{4}} \\ &= x\, \mathrm{e}^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{1} \, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\, \mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x^2}{2}} x\right) + c_2 \left(\mathrm{e}^{-\frac{x^2}{2}} x \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.57.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + xy' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

- □ Rewrite DE with series expansions

  - ○ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  - ○ Convert $\frac{d}{dx}y'$ to series expansion

    $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - ○ Shift index using $k- > k+2$

    $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\,(k a_{k+2} + a_k + a_{k+2}) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{k+1}\right]$

Solve

$$(2x^2+1)\,y''-9xy'-6y=0$$

1.58.1 Solved as second order ode using Kovacic algorithm

Time used: 0.507 (sec)

Writing the ode as

$$(2x^2+1)\,y''-9xy'-6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2+1 \\ B &= -9x \\ C &= -6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{165x^2 + 6}{4\left(2x^2 + 1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 165x^2 + 6$$
$$t = 4\left(2x^2 + 1\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{165x^2 + 6}{4\left(2x^2 + 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 104: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2+1)^2$. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{153}{64\left(x - \frac{i\sqrt{2}}{2}\right)^2} + \frac{153}{64\left(x + \frac{i\sqrt{2}}{2}\right)^2} - \frac{177i\sqrt{2}}{64\left(x - \frac{i\sqrt{2}}{2}\right)} + \frac{177i\sqrt{2}}{64\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{153}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{9}{8} \end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{153}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{9}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{165x^2 + 6}{4\left(2x^2+1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{165}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{15}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{11}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{165x^2 + 6}{4\left(2x^2+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{17}{8}$	$-\frac{9}{8}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{17}{8}$	$-\frac{9}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{15}{4}$	$-\frac{11}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{15}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{15}{4} - \left(-\frac{9}{4}\right) \\
&= 6
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{9}{8\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x + \frac{i\sqrt{2}}{2}\right)} + (0) \\
&= -\frac{9}{8\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x + \frac{i\sqrt{2}}{2}\right)} \\
&= -\frac{9x}{4x^2 + 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 6$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^6 + a_5 x^5 + a_4 x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(30x^4 + 20x^3 a_5 + 12x^2 a_4 + 6x a_3 + 2a_2\right) + 2\left(-\frac{9}{8\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x + \frac{i\sqrt{2}}{2}\right)} \right) \left(6x^5 + 5x^4 a_5 + 4x^3 a_4 + 3x\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{3}, a_1 = 0, a_2 = 1, a_3 = 0, a_4 = \frac{5}{3}, a_5 = 0\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^6 + \frac{5}{3}x^4 + x^2 + \frac{1}{3}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^6 + \frac{5}{3}x^4 + x^2 + \frac{1}{3}\right) \mathrm{e}^{\int \left(-\frac{9}{8\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x+\frac{i\sqrt{2}}{2}\right)}\right) dx} \\
&= \left(x^6 + \frac{5}{3}x^4 + x^2 + \frac{1}{3}\right) \frac{1}{\left(\left(i\sqrt{2} - 2x\right)\left(2x + i\sqrt{2}\right)\right)^{9/8}} \\
&= \frac{-3x^6 - 5x^4 - 3x^2 - 1}{\left(-4x^2 - 2\right)^{1/8}\left(12x^2 + 6\right)}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-9x}{2x^2+1} \, dx} \\
&= z_1 e^{\frac{9\ln\left(2x^2+1\right)}{8}} \\
&= z_1 \left(\left(2x^2 + 1\right)^{9/8}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = -\frac{2^{7/8}\left(4x^2 + 2\right)^{1/8}\left(3x^6 + 5x^4 + 3x^2 + 1\right)}{12\left(-4x^2 - 2\right)^{1/8}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-9x}{2x^2+1} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{9\ln\left(2x^2+1\right)}{4}}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\int \frac{36\left(2x^2 + 1\right)^{9/4} 2^{1/4}\left(-4x^2 - 2\right)^{1/4}}{\left(4x^2 + 2\right)^{1/4}\left(3x^6 + 5x^4 + 3x^2 + 1\right)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(-\frac{2^{7/8}(4x^2+2)^{1/8}\,(3x^6+5x^4+3x^2+1)}{12\,(-4x^2-2)^{1/8}}\right) + c_2\left(-\frac{2^{7/8}(4x^2+2)^{1/8}\,(3x^6+5x^4+3x^2+1)}{12\,(-4x^2-2)^{1/8}}\left(\int \frac{36}{(4x^2}\right.\right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

Solve

$$\left(2x^2-8x+11\right)y''-16(x-2)\,y'+36y=0$$

1.59.1 Solved as second order ode using Kovacic algorithm

Time used: 0.627 (sec)

Writing the ode as

$$\left(2x^2-8x+11\right)y''+(-16x+32)\,y'+36y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2-8x+11 \\ B &= -16x+32 \\ C &= 36 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{8x^2 - 32x - 100}{(2x^2 - 8x + 11)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 8x^2 - 32x - 100$$
$$t = (2x^2 - 8x + 11)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{8x^2 - 32x - 100}{(2x^2 - 8x + 11)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 105: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 - 8x + 11)^2$. There is a pole at $x = 2 + \frac{i\sqrt{6}}{2}$ of order 2. There is a pole at $x = 2 - \frac{i\sqrt{6}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{\left(x - 2 - \frac{i\sqrt{6}}{2}\right)^2} + \frac{6}{\left(x - 2 + \frac{i\sqrt{6}}{2}\right)^2} + \frac{5i\sqrt{6}}{3\left(x - 2 - \frac{i\sqrt{6}}{2}\right)} - \frac{5i\sqrt{6}}{3\left(x - 2 + \frac{i\sqrt{6}}{2}\right)}$$

For the pole at $x = 2 + \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x - 2 - \frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

For the pole at $x = 2 - \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x - 2 + \frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{8x^2 - 32x - 100}{(2x^2 - 8x + 11)^2}$$

Since the gcd$(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{8x^2 - 32x - 100}{(2x^2 - 8x + 11)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$2 + \frac{i\sqrt{6}}{2}$	2	0	3	-2
$2 - \frac{i\sqrt{6}}{2}$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{2}{x - 2 - \frac{i\sqrt{6}}{2}} + \frac{3}{x - 2 + \frac{i\sqrt{6}}{2}} + (0) \\
&= -\frac{2}{x - 2 - \frac{i\sqrt{6}}{2}} + \frac{3}{x - 2 + \frac{i\sqrt{6}}{2}} \\
&= \frac{-5i\sqrt{6} + 2x - 4}{2x^2 - 8x + 11}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{2}{x - 2 - \frac{i\sqrt{6}}{2}} + \frac{3}{x - 2 + \frac{i\sqrt{6}}{2}} \right)(1) + \left(\left(\frac{2}{\left(x - 2 - \frac{i\sqrt{6}}{2}\right)^2} - \frac{3}{\left(x - 2 + \frac{i\sqrt{6}}{2}\right)^2} \right) + \left(-\frac{2}{x - 2 - \frac{i\sqrt{6}}{2}}\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{ a_0 = -\frac{5i\sqrt{6}}{2} - 2 \right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - 2 - \frac{5i\sqrt{6}}{2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \,dx} \\
&= \left(x-2-\frac{5i\sqrt{6}}{2}\right) \mathrm{e}^{\int \left(-\frac{2}{x-2-\frac{i\sqrt{6}}{2}}+\frac{3}{x-2+\frac{i\sqrt{6}}{2}}\right)dx} \\
&= \left(x-2-\frac{5i\sqrt{6}}{2}\right) \mathrm{e}^{\frac{\ln\left(4x^2-16x+22\right)}{2}-5i\arctan\left(\frac{(2x-4)\sqrt{6}}{6}\right)} \\
&= \frac{9\left(5\sqrt{6}+2ix-4i\right)\left(2x^2-8x+11\right)^3\sqrt{6}}{2\left(-x\sqrt{6}+2\sqrt{6}+3i\right)^5}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-16x+32}{2x^2-8x+11}\,dx} \\
&= z_1 e^{2\ln\left(2x^2-8x+11\right)} \\
&= z_1\left(\left(2x^2-8x+11\right)^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{9\left(2x^2-8x+11\right)^5\left(5\sqrt{6}+2ix-4i\right)\sqrt{6}}{2\left(x\sqrt{6}-2\sqrt{6}-3i\right)^5}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-16x+32}{2x^2-8x+11}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln\left(2x^2-8x+11\right)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(-\frac{10i\sqrt{6}}{27\left(2x-4+i\sqrt{6}\right)^4}+\frac{8i\sqrt{6}}{729\left(2x-4+i\sqrt{6}\right)^2}-\frac{16}{15\left(2x-4+i\sqrt{6}\right)^5}\right. \\
&\quad\left.+\frac{22}{81\left(2x-4+i\sqrt{6}\right)^3}+\frac{4}{2187\left(2x-4+i\sqrt{6}\right)}-\frac{4}{2187\left(-5i\sqrt{6}+2x-4\right)}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{9(2x^2-8x+11)^5\left(5\sqrt{6}+2ix-4i\right)\sqrt{6}}{2\left(x\sqrt{6}-2\sqrt{6}-3i\right)^5}\right) \\
&\quad + c_2\left(\frac{9(2x^2-8x+11)^5\left(5\sqrt{6}+2ix-4i\right)\sqrt{6}}{2\left(x\sqrt{6}-2\sqrt{6}-3i\right)^5}\left(-\frac{10i\sqrt{6}}{27\left(2x-4+i\sqrt{6}\right)^4}\right.\right. \\

Will add steps showing solving for IC soon.

1.59.2 Maple step by step solution

Let's solve

$(2x^2-8x+11)\left(\frac{d}{dx}y'\right)-16(x-2)\,y'+36y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{36y}{2x^2-8x+11}+\frac{16(x-2)y'}{2x^2-8x+11}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'-\frac{16(x-2)y'}{2x^2-8x+11}+\frac{36y}{2x^2-8x+11}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=-\frac{16(x-2)}{2x^2-8x+11}, P_3(x)=\frac{36}{2x^2-8x+11}\right]$

- ◦ $\left(x-2+\frac{\mathrm{I}\sqrt{6}}{2}\right)\cdot P_2(x)$ is analytic at $x=2-\frac{\mathrm{I}\sqrt{6}}{2}$

  $\left(\left(x-2+\frac{\mathrm{I}\sqrt{6}}{2}\right)\cdot P_2(x)\right)\bigg|_{x=2-\frac{\mathrm{I}\sqrt{6}}{2}}=0$

- ◦ $\left(x-2+\frac{\mathrm{I}\sqrt{6}}{2}\right)^2\cdot P_3(x)$ is analytic at $x=2-\frac{\mathrm{I}\sqrt{6}}{2}$

$$\left(\left(x-2+\frac{I\sqrt{6}}{2}\right)^2\cdot P_3(x)\right)\bigg|_{x=2-\frac{I\sqrt{6}}{2}}=0$$

- $x=2-\frac{I\sqrt{6}}{2}$is a regular singular point
  Check to see if x_0 is a regular singular point
  $x_0=2-\frac{I\sqrt{6}}{2}$

- Multiply by denominators
  $(2x^2-8x+11)\left(\frac{d}{dx}y'\right)+(-16x+32)\,y'+36y=0$
- Change variables using $x=u+2-\frac{I\sqrt{6}}{2}$ so that the regular singular point is at $u=0$
  $(2u^2-2\,Iu\sqrt{6})\left(\frac{d}{du}\frac{d}{du}y(u)\right)+\left(-16u+8\,I\sqrt{6}\right)\left(\frac{d}{du}y(u)\right)+36y(u)=0$
- Assume series solution for $y(u)$
  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$
  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
- Shift index using $k->k+1-m$
  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
- Convert $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m=1..2$
  $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$
- Shift index using $k->k+2-m$
  $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions
  $-2\,I\sqrt{6}\,r(r-5)\,a_0u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2\,I\sqrt{6}\,(k+1+r)\,(k-4+r)\,a_{k+1}+2a_k(k+r-3)\,(k+r-\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-2\,I\sqrt{6}\,r(r-5)=0$
- Values of r that satisfy the indicial equation
  $r\in\{0,5\}$
- Each term in the series must be 0, giving the recursion relation
  $-2\,I\sqrt{6}\,(k+1+r)\,(k-4+r)\,a_{k+1}+2a_k(k+r-3)\,(k+r-6)=0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k (k^2+2kr+r^2-9k-9r+18)\sqrt{6}}{k^2+2kr+r^2-3k-3r-4}$

- Recursion relation for $r = 0$; series terminates at $k = 3$

$a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k (k^2-9k+18)\sqrt{6}}{k^2-3k-4}$

- Apply recursion relation for $k = 0$

$a_1 = \frac{3\,\mathrm{I}}{4} a_0 \sqrt{6}$

- Apply recursion relation for $k = 1$

$a_2 = \frac{5\,\mathrm{I}}{18} a_1 \sqrt{6}$

- Express in terms of a_0

$a_2 = -\frac{5a_0}{4}$

- Apply recursion relation for $k = 2$

$a_3 = \frac{\mathrm{I}}{9} a_2 \sqrt{6}$

- Express in terms of a_0

$a_3 = -\frac{5\,\mathrm{I}}{36} a_0 \sqrt{6}$

- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

$y(u) = a_0 \cdot \left(1 + \frac{3\,\mathrm{I}\sqrt{6}\,u}{4} - \frac{5u^2}{4} - \frac{5\,\mathrm{I}\sqrt{6}\,u^3}{36}\right)$

- Revert the change of variables $u = x - 2 + \frac{\mathrm{I}\sqrt{6}}{2}$

$\left[y = -\frac{\mathrm{I}}{72} a_0 \sqrt{6}\,(10x^3 - 60x^2 + 111x - 62)\right]$

- Recursion relation for $r = 5$; series terminates at $k = 1$

$a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k (k^2+k-2)\sqrt{6}}{k^2+7k+6}$

- Apply recursion relation for $k = 0$

$a_1 = \frac{\mathrm{I}}{18} a_0 \sqrt{6}$

- Terminating series solution of the ODE for $r = 5$. Use reduction of order to find the second li

$y(u) = a_0 \cdot \left(1 + \frac{\mathrm{I}\sqrt{6}\,u}{18}\right)$

- Revert the change of variables $u = x - 2 + \frac{\mathrm{I}\sqrt{6}}{2}$

$\left[y = a_0 \left(\frac{5}{6} + \frac{\mathrm{I}(x-2)\sqrt{6}}{18}\right)\right]$

- Combine solutions and rename parameters

$\left[y = -\frac{\mathrm{I} a_0 \sqrt{6}\,(10x^3-60x^2+111x-62)}{72} + b_0 \left(\frac{5}{6} + \frac{\mathrm{I}(x-2)\sqrt{6}}{18}\right)\right]$

1.60 problem 62

Internal problem ID [8198]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 62
Date solved : `Monday, October 21, 2024 at 04:55:14 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + (x-3)\,y' + 3y = 0$$

1.60.1 Solved as second order ode using Kovacic algorithm

Time used: 0.315 (sec)

Writing the ode as

$$y'' + (x-3)\,y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x-3 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6x - 1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 6x - 1$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 107: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 2\\ &= -2\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\ &= \sum_{i=0}^{1} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2} - \frac{5}{2x} - \frac{15}{2x^2} - \frac{115}{4x^3} - \frac{495}{4x^4} - \frac{2285}{4x^5} - \frac{11055}{4x^6} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i\\ &= \frac{x}{2} - \frac{3}{2} \qquad (10)\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}x^2 - \frac{3}{2}x + \frac{9}{4}$$

This shows that the coefficient of 1 in the above is $\frac{9}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 6x - 1}{4} \\ &= Q + \frac{R}{4} \\ &= \left(-\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x\right) + (0) \\ &= -\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{1}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{4}\right) - \left(\frac{9}{4}\right) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} - \frac{3}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= -3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}-\frac{3}{2}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2} - \frac{3}{2}\right) \\ &= \frac{3}{2} - \frac{x}{2} \\ &= \frac{3}{2} - \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{3}{2} - \frac{x}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2}\right) + \left(\frac{3}{2} - \frac{x}{2}\right)^2 - \left(-\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x\right)\right) = 0$$

$$(x+3)\, a_1 + 6x + 2a_0 + 2 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 8, a_1 = -6\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 6x + 8$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \left(x^2 - 6x + 8\right) \mathrm{e}^{\int \left(\frac{3}{2} - \frac{x}{2}\right) dx} \\
&= \left(x^2 - 6x + 8\right) \mathrm{e}^{\frac{3}{2}x - \frac{1}{4}x^2} \\
&= \left(x^2 - 6x + 8\right) \mathrm{e}^{-\frac{x(-6+x)}{4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x-3}{1}\, dx} \\
&= z_1 e^{\frac{3}{2}x - \frac{1}{4}x^2} \\
&= z_1 \left(\mathrm{e}^{-\frac{x(-6+x)}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x(-6+x)}{2}} \left(x^2 - 6x + 8\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x-3}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{1}{2}x^2 + 3x}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{1}{2}x^2 + 3x} \mathrm{e}^{x(-6+x)}}{\left(x^2 - 6x + 8\right)^2}\, dx\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x(-6+x)}{2}}\left(x^2-6x+8\right)\right) + c_2\left(\mathrm{e}^{-\frac{x(-6+x)}{2}}\left(x^2-6x+8\right)\left(\int \frac{\mathrm{e}^{-\frac{1}{2}x^2+3x}\mathrm{e}^{x(-6+x)}}{\left(x^2-6x+8\right)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.60.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + (x-3)\,y' + 3y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

  ◦ Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$

  ◦ Convert $\frac{d}{dx}y'$ to series expansion

1.61 problem 63

Internal problem ID [8199]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 63
Date solved : `Monday, October 21, 2024 at 04:55:15 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2-8x+14\right)y''-8(x-4)\,y'+20y=0$$

1.61.1 Solved as second order ode using Kovacic algorithm

Time used: 0.282 (sec)

Writing the ode as

$$\left(x^2-8x+14\right)y''+(-8x+32)\,y'+20y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-8x+14 \\ B &= -8x+32 \\ C &= 20 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{48}{(x^2 - 8x + 14)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 48$$
$$t = (x^2 - 8x + 14)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{48}{(x^2 - 8x + 14)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 109: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 8x + 14)^2$. There is a pole at $x = 4 + \sqrt{2}$ of order 2. There is a pole at $x = 4 - \sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{\left(x - 4 + \sqrt{2}\right)^2} + \frac{6}{\left(x - 4 - \sqrt{2}\right)^2} + \frac{3\sqrt{2}}{x - 4 + \sqrt{2}} - \frac{3\sqrt{2}}{x - 4 - \sqrt{2}}$$

For the pole at $x = 4 + \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-4-\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

For the pole at $x = 4 - \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-4+\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{48}{\left(x^2 - 8x + 14\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$4+\sqrt{2}$	2	0	3	-2
$4-\sqrt{2}$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{2}{x-4-\sqrt{2}} + \frac{3}{x-4+\sqrt{2}} + (-)(0) \\
&= -\frac{2}{x-4-\sqrt{2}} + \frac{3}{x-4+\sqrt{2}} \\
&= \frac{x-4-5\sqrt{2}}{x^2-8x+14}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{2}{x-4-\sqrt{2}} + \frac{3}{x-4+\sqrt{2}}\right)(0) + \left(\left(\frac{2}{\left(x-4-\sqrt{2}\right)^2} - \frac{3}{\left(x-4+\sqrt{2}\right)^2}\right) + \left(-\frac{2}{x-4-\sqrt{2}} + \right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{2}{x-4-\sqrt{2}} + \frac{3}{x-4+\sqrt{2}}\right) dx} \\
&= \frac{\left(x-4+\sqrt{2}\right)^3}{\left(-x+4+\sqrt{2}\right)^2}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-8x+32}{x^2-8x+14}\, dx} \\
&= z_1 e^{2\ln(x^2-8x+14)} \\
&= z_1\left(\left(x^2-8x+14\right)^2\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{(x^2 - 8x + 14)^2 \left(x - 4 + \sqrt{2}\right)^3}{\left(-x + 4 + \sqrt{2}\right)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-8x+32}{x^2-8x+14}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{4\ln(x^2-8x+14)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{4\sqrt{2}}{\left(x - 4 + \sqrt{2}\right)^2} + \frac{16\sqrt{2}}{\left(x - 4 + \sqrt{2}\right)^4} - \frac{64}{5\left(x - 4 + \sqrt{2}\right)^5} - \frac{16}{\left(x - 4 + \sqrt{2}\right)^3} \right. \\
&\qquad \left. - \frac{1}{x - 4 + \sqrt{2}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(x^2 - 8x + 14)^2 \left(x - 4 + \sqrt{2}\right)^3}{\left(-x + 4 + \sqrt{2}\right)^2}\right) \\
&\quad + c_2 \left(\frac{(x^2 - 8x + 14)^2 \left(x - 4 + \sqrt{2}\right)^3}{\left(-x + 4 + \sqrt{2}\right)^2} \left(\frac{4\sqrt{2}}{\left(x - 4 + \sqrt{2}\right)^2} + \frac{16\sqrt{2}}{\left(x - 4 + \sqrt{2}\right)^4} \right.\right. \\
&\qquad \left.\left. - \frac{64}{5\left(x - 4 + \sqrt{2}\right)^5} - \frac{16}{\left(x - 4 + \sqrt{2}\right)^3} - \frac{1}{x - 4 + \sqrt{2}}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.61.2 Maple step by step solution

Let's solve

$(x^2-8x+14)\left(\frac{d}{dx}y'\right)-8(x-4)\,y'+20y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{20y}{x^2-8x+14}+\frac{8(x-4)y'}{x^2-8x+14}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'-\frac{8(x-4)y'}{x^2-8x+14}+\frac{20y}{x^2-8x+14}=0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=-\frac{8(x-4)}{x^2-8x+14},P_3(x)=\frac{20}{x^2-8x+14}\right]$

- ○ $(x-4+\sqrt{2})\cdot P_2(x)$ is analytic at $x=4-\sqrt{2}$

  $\left((x-4+\sqrt{2})\cdot P_2(x)\right)\Big|_{x=4-\sqrt{2}}=0$

- ○ $(x-4+\sqrt{2})^2\cdot P_3(x)$ is analytic at $x=4-\sqrt{2}$

  $\left((x-4+\sqrt{2})^2\cdot P_3(x)\right)\Big|_{x=4-\sqrt{2}}=0$

- ○ $x=4-\sqrt{2}$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=4-\sqrt{2}$

- Multiply by denominators

$(x^2-8x+14)\left(\frac{d}{dx}y'\right)+(-8x+32)\,y'+20y=0$

- Change variables using $x=u+4-\sqrt{2}$ so that the regular singular point is at $u=0$

$(u^2-2u\sqrt{2})\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-8u+8\sqrt{2})\left(\frac{d}{du}y(u)\right)+20y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-2\sqrt{2}\,(r-5)\, r a_0 u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2\sqrt{2}\,(k+r-4)\,(k+1+r)\, a_{k+1} + a_k(k+r-4)\,(k+r-5)\right)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2\sqrt{2}\,(r-5)\, r = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 5\}$$

- Each term in the series must be 0, giving the recursion relation

$$\left(-2a_{k+1}(k+1+r)\sqrt{2} + a_k(k+r-5)\right)(k+r-4) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k(k+r-5)\sqrt{2}}{4(k+1+r)}$$

- Recursion relation for $r = 0$; series terminates at $k = 5$

$$a_{k+1} = \frac{a_k(k-5)\sqrt{2}}{4(k+1)}$$

- Apply recursion relation for $k = 0$

$$a_1 = -\frac{5a_0\sqrt{2}}{4}$$

- Apply recursion relation for $k = 1$

$$a_2 = -\frac{a_1\sqrt{2}}{2}$$

- Express in terms of a_0

$$a_2 = \frac{5a_0}{4}$$

- Apply recursion relation for $k = 2$

$$a_3 = -\frac{a_2\sqrt{2}}{4}$$

- Express in terms of a_0

$$a_3 = -\frac{5a_0\sqrt{2}}{16}$$

- Apply recursion relation for $k = 3$

$$a_4 = -\frac{a_3\sqrt{2}}{8}$$

- Express in terms of a_0

  $a_4 = \frac{5a_0}{64}$
- Apply recursion relation for $k = 4$

  $a_5 = -\frac{a_4\sqrt{2}}{20}$
- Express in terms of a_0

  $a_5 = -\frac{a_0\sqrt{2}}{256}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

  $y(u) = a_0 \cdot \left(1 - \frac{5u\sqrt{2}}{4} + \frac{5u^2}{4} - \frac{5\sqrt{2}\,u^3}{16} + \frac{5u^4}{64} - \frac{\sqrt{2}\,u^5}{256}\right)$
- Revert the change of variables $u = x - 4 + \sqrt{2}$

  $\left[y = a_0\left(\frac{(-x^5+20x^4-180x^3+880x^2-2260x+2384)\sqrt{2}}{256} + \frac{5x^4}{128} - \frac{5x^3}{8} + \frac{125x^2}{32} - \frac{45x}{4} + \frac{401}{32}\right)\right]$
- Recursion relation for $r = 5$

  $a_{k+1} = \frac{a_k k\sqrt{2}}{4(k+6)}$
- Solution for $r = 5$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+5}, a_{k+1} = \frac{a_k k\sqrt{2}}{4(k+6)}\right]$
- Revert the change of variables $u = x - 4 + \sqrt{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k\left(x - 4 + \sqrt{2}\right)^{k+5}, a_{k+1} = \frac{a_k k\sqrt{2}}{4(k+6)}\right]$
- Combine solutions and rename parameters

  $\left[y = a_0\left(\frac{(-x^5+20x^4-180x^3+880x^2-2260x+2384)\sqrt{2}}{256} + \frac{5x^4}{128} - \frac{5x^3}{8} + \frac{125x^2}{32} - \frac{45x}{4} + \frac{401}{32}\right) + \left(\sum_{k=0}^{\infty} b_k\left(x - 4 + \right.\right.\right.$

Solve

$$\left(2x^2+4x+5\right)y''-20(x+1)\,y'+60y=0$$

1.62.1 Solved as second order ode using Kovacic algorithm

Time used: 0.597 (sec)

Writing the ode as

$$\left(2x^2+4x+5\right)y''+(-20x-20)\,y'+60y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x^2+4x+5\\B&=-20x-20\\C&=60\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-210}{(2x^2 + 4x + 5)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -210$$
$$t = (2x^2 + 4x + 5)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{210}{(2x^2 + 4x + 5)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 111: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 + 4x + 5)^2$. There is a pole at $x = -1 + \frac{i\sqrt{6}}{2}$ of order 2. There is a pole at $x = -1 - \frac{i\sqrt{6}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4\left(x+1-\frac{i\sqrt{6}}{2}\right)^2} + \frac{35}{4\left(x+1+\frac{i\sqrt{6}}{2}\right)^2} + \frac{35i\sqrt{6}}{12\left(x+1-\frac{i\sqrt{6}}{2}\right)} - \frac{35i\sqrt{6}}{12\left(x+1+\frac{i\sqrt{6}}{2}\right)}$$

For the pole at $x = -1 + \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x+1-\frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = -1 - \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x+1+\frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{210}{(2x^2 + 4x + 5)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-1 + \frac{i\sqrt{6}}{2}$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
$-1 - \frac{i\sqrt{6}}{2}$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)} + (-)(0) \\
&= -\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)} \\
&= \frac{-6i\sqrt{6}+2x+2}{2x^2+4x+5}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)}\right)(0) + \left(\left(\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)^2} - \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)^2}\right) + \left(-\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)}\right) dx} \\
&= \frac{27\sqrt{2}\,(2x^2+4x+5)^{7/2}}{\left(3+i\,(x+1)\sqrt{6}\right)^6}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-20x-20}{2x^2+4x+5}\, dx} \\
&= z_1 e^{\frac{5\ln\left(2x^2+4x+5\right)}{2}} \\
&= z_1 \left(\left(2x^2+4x+5\right)^{5/2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = -\frac{\left(2x^2+4x+5\right)^6 \sqrt{2}}{27 \left(i - \frac{(x+1)\sqrt{2}\,\sqrt{3}}{3}\right)^6}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-20x-20}{2x^2+4x+5}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{5\ln(2x^2+4x+5)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\frac{1}{2}x^5 + \frac{5}{2}x^4 + \frac{5}{2}x^3 - \frac{5}{2}x^2 - \frac{31}{8}x - \frac{7}{8}}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)^6}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(-\frac{\left(2x^2+4x+5\right)^6 \sqrt{2}}{27 \left(i - \frac{(x+1)\sqrt{2}\,\sqrt{3}}{3}\right)^6}\right) \\
&\quad + c_2 \left(-\frac{\left(2x^2+4x+5\right)^6 \sqrt{2}}{27 \left(i - \frac{(x+1)\sqrt{2}\,\sqrt{3}}{3}\right)^6} \left(-\frac{\frac{1}{2}x^5 + \frac{5}{2}x^4 + \frac{5}{2}x^3 - \frac{5}{2}x^2 - \frac{31}{8}x - \frac{7}{8}}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)^6}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.62.2 Maple step by step solution

Let's solve

$(2x^2+4x+5)\left(\frac{d}{dx}y'\right)-20(x+1)\,y'+60y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{60y}{2x^2+4x+5}+\frac{20(x+1)y'}{2x^2+4x+5}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'-\frac{20(x+1)y'}{2x^2+4x+5}+\frac{60y}{2x^2+4x+5}=0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

$\left[P_2(x)=-\frac{20(x+1)}{2x^2+4x+5},P_3(x)=\frac{60}{2x^2+4x+5}\right]$

- ○ $\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right)\cdot P_2(x)$ is analytic at $x=-1-\frac{\mathrm{I}\sqrt{6}}{2}$

$\left(\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right)\cdot P_2(x)\right)\bigg|_{x=-1-\frac{\mathrm{I}\sqrt{6}}{2}}=0$

- ○ $\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right)^2\cdot P_3(x)$ is analytic at $x=-1-\frac{\mathrm{I}\sqrt{6}}{2}$

$\left(\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right)^2\cdot P_3(x)\right)\bigg|_{x=-1-\frac{\mathrm{I}\sqrt{6}}{2}}=0$

- ○ $x=-1-\frac{\mathrm{I}\sqrt{6}}{2}$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1-\frac{\mathrm{I}\sqrt{6}}{2}$

- Multiply by denominators

$(2x^2+4x+5)\left(\frac{d}{dx}y'\right)+(-20x-20)\,y'+60y=0$

- Change variables using $x=u-1-\frac{\mathrm{I}\sqrt{6}}{2}$ so that the regular singular point is at $u=0$

$\left(2u^2-2\,\mathrm{I}u\sqrt{6}\right)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+\left(-20u+10\,\mathrm{I}\sqrt{6}\right)\left(\frac{d}{du}y(u)\right)+60y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-2\,\mathrm{I}\sqrt{6}\, r(r-6)\, a_0 u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2\,\mathrm{I}\sqrt{6}\,(k+1+r)\,(k+r-5)\, a_{k+1} + 2a_k(k+r-5)\,(k+r-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2\,\mathrm{I}\sqrt{6}\, r(r-6) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 6\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2(k+r-5)\left(\mathrm{I}(k+1+r)\, a_{k+1}\sqrt{6} - a_k(k+r-6)\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k(k+r-6)\sqrt{6}}{k+1+r}$$

- Recursion relation for $r = 0$; series terminates at $k = 6$

$$a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k(k-6)\sqrt{6}}{k+1}$$

- Recursion relation that defines the terminating series solution of the ODE for $r = 0$

$$\left[y(u) = \sum_{k=0}^{5} a_k u^k, a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k(k-6)\sqrt{6}}{k+1}\right]$$

- Revert the change of variables $u = x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}$

$$\left[y = \sum_{k=0}^{5} a_k \left(x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}\right)^k, a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k(k-6)\sqrt{6}}{k+1}\right]$$

- Recursion relation for $r = 6$

$$a_{k+1} = \frac{-\frac{\mathrm{I}}{6} a_k k\sqrt{6}}{k+7}$$

- Solution for $r = 6$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+6}, a_{k+1}=\frac{-\frac{I}{6} a_k k\sqrt{6}}{k+7}\right]$$

- Revert the change of variables $u=x+1+\frac{I\sqrt{6}}{2}$

$$\left[y=\sum_{k=0}^{\infty} a_k \left(x+1+\frac{I\sqrt{6}}{2}\right)^{k+6}, a_{k+1}=\frac{-\frac{I}{6} a_k k\sqrt{6}}{k+7}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{5} a_k \left(x+1+\frac{I\sqrt{6}}{2}\right)^{k}\right)+\left(\sum_{k=0}^{\infty} b_k \left(x+1+\frac{I\sqrt{6}}{2}\right)^{k+6}\right), a_{k+1}=\frac{-\frac{I}{6} a_k (k-6)\sqrt{6}}{k+1}, b_{k+1}=\frac{-\frac{I}{6} b_k k\sqrt{6}}{k+7}\right]$$

Solve

$$\left(x^3+1\right) y''+7x^2y'+9xy=0$$

1.63.1 Solved as second order ode using Kovacic algorithm

Time used: 0.431 (sec)

Writing the ode as

$$\left(x^3+1\right) y''+7x^2y'+9xy=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^3+1 \\ B &= 7x^2 \\ C &= 9x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x(x^3 + 8)}{4\left(x^3 + 1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -x\left(x^3 + 8\right)$$
$$t = 4\left(x^3 + 1\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{x(x^3 + 8)}{4\left(x^3 + 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 113: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 6 - 4\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+1)^2$. There is a pole at $x = -1$ of order 2. There is a pole at $x = \frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = \frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned}r = {}& \frac{5}{18(x+1)} + \frac{7}{36(x+1)^2} + \frac{7}{36\left(x - \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2}\\ &+ \frac{7}{36\left(x - \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{5}{36} + \frac{5i\sqrt{3}}{36}}{x - \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{-\frac{5}{36} - \frac{5i\sqrt{3}}{36}}{x - \frac{1}{2} + \frac{i\sqrt{3}}{2}}\end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}\end{aligned}$$

For the pole at $x = \frac{1}{2} - \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}\end{aligned}$$

For the pole at $x = \frac{1}{2} + \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{x(x^3+8)}{4\left(x^3+1\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{x(x^3+8)}{4\left(x^3+1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
$\frac{1}{2} - \frac{i\sqrt{3}}{2}$	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
$\frac{1}{2} + \frac{i\sqrt{3}}{2}$	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{6(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)} + (-)(0) \\
&= -\frac{1}{6(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)} \\
&= -\frac{x^2}{2x^3+2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{6(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)}\right)(1) + \left(\left(\frac{1}{6(x+1)^2} + \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2} + \right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, \mathrm{e}^{\int \left(-\frac{1}{6(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)}\right) dx} \\
&= (x) \frac{1}{\left((x+1)\left(2x-1+i\sqrt{3}\right)\left(i\sqrt{3}-2x+1\right)\right)^{1/6}} \\
&= \frac{x}{\left((x+1)\left(2x-1+i\sqrt{3}\right)\left(i\sqrt{3}-2x+1\right)\right)^{1/6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^2}{x^3+1} \, dx} \\
&= z_1 e^{-\frac{7\ln\left(x^3+1\right)}{6}} \\
&= z_1 \left(\frac{1}{\left(x^3+1\right)^{7/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{\left(x^3+1\right)^{7/6}\left(-4x^3-4\right)^{1/6}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{7x^2}{x^3+1}\,dx}}{(y_1)^2}\,dx$$

$$= y_1 \int \frac{e^{-\frac{7\ln\left(x^3+1\right)}{3}}}{(y_1)^2}\,dx$$

$$= y_1 \left(\int \frac{\left(-4x^3-4\right)^{1/3}}{x^2}dx\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x}{\left(x^3+1\right)^{7/6}\left(-4x^3-4\right)^{1/6}}\right) + c_2 \left(\frac{x}{\left(x^3+1\right)^{7/6}\left(-4x^3-4\right)^{1/6}}\left(\int \frac{\left(-4x^3-4\right)^{1/3}}{x^2}dx\right)\right)$$

Will add steps showing solving for IC soon.

1.63.2 Maple step by step solution

Let's solve

$\left(x^3+1\right)\left(\frac{d}{dx}y'\right) + 7x^2y' + 9xy = 0$

- Highest derivative means the order of the ODE is 2

- $(x+1)^2 \cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^3+1)\left(\frac{d}{dx}y'\right) + 7x^2y' + 9xy = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^3 - 3u^2 + 3u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (7u^2 - 14u + 7)\left(\frac{d}{du}y(u)\right) + (9u-9)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

    $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

  - Shift index using $k->k-m$

    $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

    $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(4+3r)\, u^{-1+r} + \left(a_1(1+r)(7+3r) - a_0(3r^2+11r+9)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)(3k+7\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(4+3r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{0, -\frac{4}{3}\right\}$
- Each term must be 0

  $a_1(1+r)(7+3r) - a_0(3r^2+11r+9) = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(3k+7+3r) - a_k(3k^2+6kr+3r^2+11k+11r+9) + a_{k-1}(k+2+r)^2 = 0$
- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)(3k+10+3r) - a_{k+1}\left(3(k+1)^2+6(k+1)r+3r^2+11k+20+11r\right) + a_k(k+$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+2kra_k-6kra_{k+1}+r^2a_k-3r^2a_{k+1}+6ka_k-17ka_{k+1}+6ra_k-17ra_{k+1}+9a_k-23a_{k+1}}{(k+2+r)(3k+10+3r)}$
- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+6ka_k-17ka_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)}$
- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+6ka_k-17ka_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)}, 7a_1 - 9a_0 = 0\right]$
- Revert the change of variables $u = x+1$

  $\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+6ka_k-17ka_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)}, 7a_1 - 9a_0 = 0\right]$
- Recursion relation for $r = -\frac{4}{3}$

  $a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+\frac{10}{3}ka_k-9ka_{k+1}+\frac{25}{9}a_k-\frac{17}{3}a_{k+1}}{\left(k+\frac{2}{3}\right)(3k+6)}$
- Solution for $r = -\frac{4}{3}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{4}{3}}, a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+\frac{10}{3}ka_k-9ka_{k+1}+\frac{25}{9}a_k-\frac{17}{3}a_{k+1}}{\left(k+\frac{2}{3}\right)(3k+6)}, -a_1 + \frac{a_0}{3} = 0\right]$
- Revert the change of variables $u = x+1$

  $\left[y = \sum_{k=0}^{\infty} a_k(x+1)^{k-\frac{4}{3}}, a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+\frac{10}{3}ka_k-9ka_{k+1}+\frac{25}{9}a_k-\frac{17}{3}a_{k+1}}{\left(k+\frac{2}{3}\right)(3k+6)}, -a_1 + \frac{a_0}{3} = 0\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k(x+1)^k\right) + \left(\sum_{k=0}^{\infty} b_k(x+1)^{k-\frac{4}{3}}\right), a_{k+2} = -\frac{k^2a_k-3k^2a_{k+1}+6ka_k-17ka_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)}, 7a_1\right.$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^5+1\right)y''+14x^4y'+10x^3y=0$$

1.64.1 Solved as second order ode using Kovacic algorithm

Time used: 1.118 (sec)

Writing the ode as

$$\left(2x^5+1\right)y''+14x^4y'+10x^3y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^5+1 \\ B &= 14x^4 \\ C &= 10x^3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^3(5x^5 + 6)}{(2x^5 + 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3x^3(5x^5 + 6)$$
$$t = (2x^5 + 1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^3(5x^5 + 6)}{(2x^5 + 1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 115: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 10 - 8 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^5+1)^2$. There is a pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ of order 2. There is a pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}$ of order 2. There is a pole at $x = -\frac{2^{4/5}}{2}$ of order 2. There is a pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}$ of order 2. There is a pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \text{Expression too large to display}$$

For the pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ let b be the coefficient of $\frac{1}{\left(x - \frac{2^{4/5}\sqrt{5}}{8} - \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10} \end{aligned}$$

For the pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}$ let b be the coefficient of $\frac{1}{\left(x - \frac{2^{4/5}}{8} + \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10} \end{aligned}$$

For the pole at $x = -\frac{2^{4/5}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{2^{4/5}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10}
\end{aligned}
$$

For the pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}$ let b be the coefficient of $\frac{1}{\left(x-\frac{2^{4/5}}{8}+\frac{2^{4/5}\sqrt{5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10}
\end{aligned}
$$

For the pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ let b be the coefficient of $\frac{1}{\left(x-\frac{2^{4/5}\sqrt{5}}{8}-\frac{2^{4/5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^3(5x^5+6)}{(2x^5+1)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x^3(5x^5+6)}{(2x^5+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{2^{4/5}\sqrt{5}}{8}+\frac{2^{4/5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$\frac{2^{4/5}}{8}-\frac{2^{4/5}\sqrt{5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5}}{8}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$-\frac{2^{4/5}}{2}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$\frac{2^{4/5}}{8}-\frac{2^{4/5}\sqrt{5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$\frac{2^{4/5}\sqrt{5}}{8}+\frac{2^{4/5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^- + \alpha_{c_4}^- + \alpha_{c_5}^-\right) \\ &= \frac{5}{2} - \left(\frac{3}{2}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\omega = \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + \left((-)[\sqrt{r}]_{c_4} + \frac{\alpha_{c_4}^-}{x-c_4}\right)$$
$$= \frac{3}{10\left(x - \frac{2^{4/5}\sqrt{5}}{8} - \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)} + \frac{3}{10\left(x - \frac{2^{4/5}}{8} + \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5}}{8}\right)} + \frac{}{10(}$$
$$= \frac{3}{10\left(x - \frac{2^{4/5}\sqrt{5}}{8} - \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)} + \frac{3}{10\left(x - \frac{2^{4/5}}{8} + \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5}}{8}\right)} + \frac{}{10(}$$
$$= \frac{3x^4}{2x^5+1}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) and Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$z_1(x) = pe^{\int \omega\, dx}$$
$$= (x)\, \mathrm{e}^{\int \left(\frac{3}{10\left(x - \frac{2^{4/5}\sqrt{5}}{8} - \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)} + \frac{3}{10\left(x - \frac{2^{4/5}}{8} + \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5}}{8}\right)} + \frac{3}{10\left(x + \frac{2^{4/5}}{2}\right)} + \frac{}{10\left(x - \frac{2^{4/5}}{8}\right.}\right.}$$
$$= (x)\left(\left(2^{4/5}\sqrt{5} + 2i2^{3/10}\sqrt{5-\sqrt{5}} + 2^{4/5} - 8x\right)\left(-i2^{3/10}\sqrt{5-\sqrt{5}}\sqrt{5} + 2^{4/5}\sqrt{5} - i2^{3/10}\sqrt{5-\sqrt{\right.\right.$$
$$= x8^{3/10}\left(\left(x + \frac{2^{4/5}}{2}\right)\left(i\left(\sqrt{5}+1\right)2^{3/10}\sqrt{5-\sqrt{5}} + \left(\sqrt{5}-1\right)2^{4/5} + 8x\right)\left(i2^{3/10}\sqrt{5-\sqrt{5}} + \frac{(-\sqrt{}}{}\right.\right.$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{14x^4}{2x^5+1}\,dx} \\
&= z_1 e^{-\frac{7\ln\left(2x^5+1\right)}{10}} \\
&= z_1 \left(\frac{1}{\left(2x^5+1\right)^{7/10}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x 8^{3/10} \left(1024x^5+512\right)^{3/10}}{\left(2x^5+1\right)^{7/10}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{14x^4}{2x^5+1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{7\ln\left(2x^5+1\right)}{5}}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\int \frac{8^{2/5}}{8x^2\left(1024x^5+512\right)^{3/5}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x 8^{3/10}\left(1024x^5+512\right)^{3/10}}{\left(2x^5+1\right)^{7/10}}\right) + c_2 \left(\frac{x 8^{3/10}\left(1024x^5+512\right)^{3/10}}{\left(2x^5+1\right)^{7/10}} \left(\int \frac{8^{2/5}}{8x^2\left(1024x^5+512\right)^{3/5}}dx\right)\right)

1.65 problem 67

Internal problem ID [8203]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 67
Date solved : `Monday, October 21, 2024 at 04:55:45 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + x^6 y' + 7x^5 y = 0$$

1.65.1 Solved as second order ode using Kovacic algorithm

Time used: 0.438 (sec)

Writing the ode as

$$y'' + x^6 y' + 7x^5 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x^6 \\ C &= 7x^5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^5(x^7 - 16)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^5(x^7 - 16)$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^5(x^7 - 16)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 116: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 12 \\ &= -12 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -12 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -12$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{12}{2} = 6$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{6} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^6$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x^6}{2} - \frac{4}{x} - \frac{16}{x^8} - \frac{128}{x^{15}} - \frac{1280}{x^{22}} - \frac{14336}{x^{29}} - \frac{172032}{x^{36}} - \frac{2162688}{x^{43}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 6$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{6} a_i x^i \\ &= \frac{x^6}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^5 = x^5$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^{12}}{4}$$

This shows that the coefficient of x^5 in the above is 0. Now we need to find the coefficient of x^5 in r. How this is done depends on if $v = 0$ or not. Since $v = 6$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x^5 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^5(x^7 - 16)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{1}{4}x^{12} - 4x^5\right) + (0) \\
&= \frac{1}{4}x^{12} - 4x^5
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is -4. Now b can be found.

$$\begin{aligned}
b &= (-4) - (0) \\
&= -4
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x^6}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-4}{\frac{1}{2}} - 6\right) &&= -7 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-4}{\frac{1}{2}} - 6\right) &&= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^5(x^7 - 16)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-12	$\frac{x^6}{2}$	-7	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^{-} \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x^6}{2}\right) \\ &= -\frac{x^6}{2} \\ &= -\frac{x^6}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{x^6}{2}\right)(1) + \left((-3x^5) + \left(-\frac{x^6}{2}\right)^2 - \left(\frac{x^5(x^7-16)}{4}\right)\right) = 0$$

$$x^5 a_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x) \, \mathrm{e}^{\int -\frac{x^6}{2} dx} \\
&= (x) \, \mathrm{e}^{-\frac{x^7}{14}} \\
&= x \, \mathrm{e}^{-\frac{x^7}{14}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x^6}{1} \, dx} \\
&= z_1 e^{-\frac{x^7}{14}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x^7}{14}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^7}{7}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^6}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{x^7}{7}}}{(y_1)^2} \, dx
\end{aligned}$$

$$= y_1 \left(\frac{7^{6/7}(-1)^{1/7}\left(-\frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}\right)}{(-x^7)^{6/7}} + \frac{7\,7^{1/7}(-1)^{6/7}\mathrm{e}^{\frac{x^7}{7}}}{x} + \frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}, -\frac{x^7}{7}\right)}{(-x^7)^{6/7}}\right)}{49} \right)$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-\frac{x^7}{7}} x\right) \\ &\quad + c_2 \left(\mathrm{e}^{-\frac{x^7}{7}} x \left(\frac{7^{6/7}(-1)^{1/7}\left(-\frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}\right)}{(-x^7)^{6/7}} + \frac{7\,7^{1/7}(-1)^{6/7}\mathrm{e}^{\frac{x^7}{7}}}{x} + \frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}, -\frac{x^7}{7}\right)}{(-x^7)^{6/7}}\right)}{49} \right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.65.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + x^6 y' + 7x^5 y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^5 \cdot y$ to series expansion

  $x^5 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+5}$

- ◦ Shift index using $k- >k-5$

  $x^5 \cdot y = \sum_{k=5}^{\infty} a_{k-5} x^k$

- ◦ Convert $x^6 \cdot y'$ to series expansion

  $x^6 \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^{k+5}$

- Shift index using $k->k-5$

  $$x^6 \cdot y' = \sum_{k=5}^{\infty} a_{k-5}(k-5)\, x^k$$

- Convert $\frac{d}{dx}y'$ to series expansion

  $$\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

  $$\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

  Rewrite ODE with series expansions

  $$30a_6x^4 + 20a_5x^3 + 12a_4x^2 + 6a_3x + 2a_2 + \left(\sum_{k=5}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k-5}(k+2)\right) x^k\right) = 0$$

- The coefficients of each power of x must be 0

  $[2a_2 = 0, 6a_3 = 0, 12a_4 = 0, 20a_5 = 0, 30a_6 = 0]$

- Solve for the dependent coefficient(s)

  $\{a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0, a_6 = 0\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\,(ka_{k+2} + a_{k-5} + a_{k+2}) = 0$

- Shift index using $k->k+5$

  $(k+7)\,((k+5)\, a_{k+7} + a_k + a_{k+7}) = 0$

- Recursion relation that defines the series solution to the ODE

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+7} = -\frac{a_k}{k+6}, a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0, a_6 = 0\right]$$

1.66 problem 68

Internal problem ID [8204]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 68
Date solved : `Tuesday, October 22, 2024 at 03:00:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^{8}+1\right) y''-16x^{7}y'+72x^{6}y=0$$

1.66.1 Solved as second order ode using Kovacic algorithm

Time used: 434.082 (sec)

Writing the ode as

$$\left(x^{8}+1\right) y''-16x^{7}y'+72x^{6}y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{8}+1\\ B &= -16x^{7}\\ C &= 72x^{6} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-128x^6}{(x^8+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -128x^6$$
$$t = (x^8+1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{128x^6}{(x^8+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 118: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 16 - 6 \\
&= 10
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^8+1)^2$. There is a pole at $x = \frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = \frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 10 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 10 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned}
r = {} & \frac{2}{\left(x - \frac{\sqrt{2+\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2} + \frac{2}{\left(x - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^2} + \frac{2}{\left(x + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^2} \\
& + \frac{2}{\left(x + \frac{\sqrt{2+\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2} + \frac{2}{\left(x + \frac{\sqrt{2+\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2} \\
& + \frac{2}{\left(x + \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^2} + \frac{2}{\left(x - \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^2} \\
& + \frac{2}{\left(x - \frac{\sqrt{2+\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2} + \frac{2\left(\frac{\sqrt{2+\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^7}{x - \frac{\sqrt{2+\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} + \frac{2\left(\frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^7}{x - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2+\sqrt{2}}}{2}} \\
& + \frac{2\left(-\frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^7}{x + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2+\sqrt{2}}}{2}} + \frac{2\left(-\frac{\sqrt{2+\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^7}{x + \frac{\sqrt{2+\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} + \frac{2\left(-\frac{\sqrt{2+\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^7}{x + \frac{\sqrt{2+\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}} \\
& + \frac{2\left(-\frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^7}{x + \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2+\sqrt{2}}}{2}} + \frac{2\left(\frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2+\sqrt{2}}}{2}\right)^7}{x - \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2+\sqrt{2}}}{2}} + \frac{2\left(\frac{\sqrt{2+\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}\right)^7}{x - \frac{\sqrt{2+\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}}
\end{aligned}$$

For the pole at $x = \frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = -\frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = -\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}+\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = -\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$

in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

For the pole at $x = -\frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

For the pole at $x = \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

For the pole at $x = \frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

Since the order of r at ∞ is $10 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=-\frac{128x^6}{(x^8+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1
$\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1
$-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1
$-\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1
$-\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1
$-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1
$\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1
$\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}+\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}$	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
10	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=1$ then

$$\begin{aligned}d&=\alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^- + \alpha_{c_4}^- + \alpha_{c_5}^- + \alpha_{c_6}^- + \alpha_{c_7}^- + \alpha_{c_8}^+\right)\\&=1-(-5)\\&=6\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\omega = \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + \left((-)[\sqrt{r}]_{c_4} + \frac{\alpha_{c_4}^{-}}{x-c_4}\right)$$

$$= -\frac{1}{x - \frac{\sqrt{2}\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} -}$$

$$= -\frac{1}{x - \frac{\sqrt{2}\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} -}$$

$$= \frac{((3x^6 - 3ix^4 - 3ix^2 - 3)\sqrt{2} - 3((-1+i)x^4 + 1 + i)(x^2+1))\sqrt{2-\sqrt{2}} - 3x\left(((-1+i)x^4 + 1 + i\right.}{2\left(x^2 - x\sqrt{2-\sqrt{2}} + 1\right)\left(-x(1+\sqrt{2})\sqrt{2-\sqrt{2}} + x^2 + 1\right)\left(x\sqrt{2-\sqrt{2}} + x^2 + 1\right)\left(x(1+\sqrt{2})\right.}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 6$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)p = 0 \tag{1A}$$

Let

$$p(x) = x^6 + x^5 a_5 + x^4 a_4 + a_3 x^3 + a_2 x^2 + x a_1 + a_0 \tag{2A}$$

Substituting the above in eq. (1A) and Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{i\sqrt{2} - 1 + i}{i\sqrt{2} + 1 + i}, a_1 = \frac{\left(\frac{12}{7} - \frac{12i}{7}\right)\sqrt{2}}{(i\sqrt{2} + 1 + i)\sqrt{2-\sqrt{2}}}, a_2 = -\frac{15(-\sqrt{2} - 1 + i)}{7(i\sqrt{2} + 1 + i)}, a_3 = \frac{32}{7\sqrt{2-\sqrt{2}}\,(i\sqrt{2} + 1\right.$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^6 + \frac{\left(\frac{12}{7} + \frac{12i}{7}\right)x^5\sqrt{2}}{(i\sqrt{2} + 1 + i)\sqrt{2-\sqrt{2}}} + \frac{15x^4(\sqrt{2} + 1 + i)}{7(i\sqrt{2} + 1 + i)} + \frac{32x^3}{7\sqrt{2-\sqrt{2}}\,(i\sqrt{2} + 1 + i)} - \frac{15(-\sqrt{2} - 1 +}{7(i\sqrt{2} + 1 +}$$

Therefore the first solution to the ode $z'' = rz$ is

$$z_1(x) = pe^{\int \omega\, dx}$$

$$= \left(x^6 + \frac{\left(\frac{12}{7} + \frac{12i}{7}\right)x^5\sqrt{2}}{(i\sqrt{2} + 1 + i)\sqrt{2-\sqrt{2}}} + \frac{15x^4(\sqrt{2} + 1 + i)}{7(i\sqrt{2} + 1 + i)} + \frac{32x^3}{7\sqrt{2-\sqrt{2}}\,(i\sqrt{2} + 1 + i)} - \frac{15(-\sqrt{2} - 1}{7(i\sqrt{2} +}\right.$$

$$= \left(x^6 + \frac{\left(\frac{12}{7} + \frac{12i}{7}\right)x^5\sqrt{2}}{(i\sqrt{2} + 1 + i)\sqrt{2-\sqrt{2}}} + \frac{15x^4(\sqrt{2} + 1 + i)}{7(i\sqrt{2} + 1 + i)} + \frac{32x^3}{7\sqrt{2-\sqrt{2}}\,(i\sqrt{2} + 1 + i)} - \frac{15(-\sqrt{2} - 1}{7(i\sqrt{2} +}\right.$$

$= \text{Expression too large to display}$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-16x^7}{x^8+1}\,dx} \\
&= z_1 e^{\ln(x^8+1)} \\
&= z_1 \left(x^8+1\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \text{Expression too large to display}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-16x^7}{x^8+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x^8+1)}}{(y_1)^2}\,dx \\
&= y_1(\text{Expression too large to display})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\text{Expression too large to display}) \\
&\quad + c_2(\text{Expression too large to display}(\text{Expression too large to display}))
\end{aligned}
$$

Will add steps showing solving for IC soon.

Book : Collection of Kovacic problems
Section : section 1
Problem number : 69
Date solved : `Monday, October 21, 2024 at 05:02:46 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + x^5 y' + 6x^4 y = 0$$

1.67.1 Solved as second order ode using Kovacic algorithm

Time used: 0.464 (sec)

Writing the ode as

$$y'' + x^5 y' + 6x^4 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x^5 \\ C &= 6x^4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4(x^6 - 14)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^4(x^6 - 14)$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4(x^6 - 14)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 119: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 10 \\
&= -10
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -10 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -10$ then

$$
v = \frac{-O_r(\infty)}{2} = \frac{10}{2} = 5
$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{5} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^5$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{x^5}{2} - \frac{7}{2x} - \frac{49}{4x^7} - \frac{343}{4x^{13}} - \frac{12005}{16x^{19}} - \frac{117649}{16x^{25}} - \frac{2470629}{32x^{31}} - \frac{27176919}{32x^{37}} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{2}
$$

From Eq. (9) the sum up to $v = 5$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{5} a_i x^i \\
&= \frac{x^5}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^4 = x^4$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^{10}}{4}$$

This shows that the coefficient of x^4 in the above is 0. Now we need to find the coefficient of x^4 in r. How this is done depends on if $v = 0$ or not. Since $v = 5$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x^4 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4(x^6 - 14)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{1}{4}x^{10} - \frac{7}{2}x^4\right) + (0) \\
&= \frac{1}{4}x^{10} - \frac{7}{2}x^4
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{7}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{7}{2}\right) - (0) \\
&= -\frac{7}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x^5}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{7}{2}}{\frac{1}{2}} - 5\right) &&= -6 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{7}{2}}{\frac{1}{2}} - 5\right) &&= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4(x^6 - 14)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-10	$\frac{x^5}{2}$	-6	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x^5}{2}\right) \\ &= -\frac{x^5}{2} \\ &= -\frac{x^5}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{x^5}{2}\right)(1) + \left(\left(-\frac{5x^4}{2}\right) + \left(-\frac{x^5}{2}\right)^2 - \left(\frac{x^4(x^6-14)}{4}\right)\right) = 0$$

$$x^4 a_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= (x)\, \mathrm{e}^{\int -\frac{x^5}{2} dx} \\ &= (x)\, \mathrm{e}^{-\frac{x^6}{12}} \\ &= x\, \mathrm{e}^{-\frac{x^6}{12}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^5}{1}\, dx} \\ &= z_1 e^{-\frac{x^6}{12}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x^6}{12}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^6}{6}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^5}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^6}{6}}}{(y_1)^2}\, dx \end{aligned}$$

$$
= y_1 \left(\frac{6^{5/6}(-1)^{1/6}\left(-\frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}\right)}{(-x^6)^{5/6}} + \frac{6\,6^{1/6}(-1)^{5/6}\mathrm{e}^{\frac{x^6}{6}}}{x} + \frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}, -\frac{x^6}{6}\right)}{(-x^6)^{5/6}}\right)}{36}\right)
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x^6}{6}} x\right) \\
&\quad + c_2\left(\mathrm{e}^{-\frac{x^6}{6}} x \left(\frac{6^{5/6}(-1)^{1/6}\left(-\frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}\right)}{(-x^6)^{5/6}} + \frac{6\,6^{1/6}(-1)^{5/6}\mathrm{e}^{\frac{x^6}{6}}}{x} + \frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}, -\frac{x^6}{6}\right)}{(-x^6)^{5/6}}\right)}{36}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.67.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + x^5 y' + 6x^4 y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  - Convert $x^4 \cdot y$ to series expansion

    $x^4 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+4}$

  - Shift index using $k- >k-4$

    $x^4 \cdot y = \sum_{k=4}^{\infty} a_{k-4} x^k$

  - Convert $x^5 \cdot y'$ to series expansion

    $x^5 \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^{k+4}$

- Shift index using $k->k-4$

  $$x^5 \cdot y' = \sum_{k=4}^{\infty} a_{k-4}(k-4)\, x^k$$

- Convert $\frac{d}{dx}y'$ to series expansion

  $$\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

  $$\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

  Rewrite ODE with series expansions

  $$20a_5x^3 + 12a_4x^2 + 6a_3x + 2a_2 + \left(\sum_{k=4}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k-4}(k+2)\right) x^k\right) = 0$$

- The coefficients of each power of x must be 0

  $$[2a_2 = 0, 6a_3 = 0, 12a_4 = 0, 20a_5 = 0]$$

- Solve for the dependent coefficient(s)

  $$\{a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0\}$$

- Each term in the series must be 0, giving the recursion relation

  $$(k+2)\,(ka_{k+2} + a_{k-4} + a_{k+2}) = 0$$

- Shift index using $k->k+4$

  $$(k+6)\,((k+4)\,a_{k+6} + a_k + a_{k+6}) = 0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+6} = -\frac{a_k}{k+5}, a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0\right]$$

1.68 problem 70

Internal problem ID [8206]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 70
Date solved : `Monday, October 21, 2024 at 05:02:48 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1+3x)\,y''+xy'+2y=0$$

1.68.1 Solved as second order ode using Kovacic algorithm

Time used: 31.984 (sec)

Writing the ode as

$$(1+3x)\,y''+xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=1+3x\\ B&=x\\ C&=2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 24x - 6}{4(1+3x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 24x - 6$$
$$t = 4(1+3x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 24x - 6}{4(1+3x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 121: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 2 \\
&= 0
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(1+3x)^2$. There is a pole at $x = -\frac{1}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{19}{324\left(x+\frac{1}{3}\right)^2} - \frac{37}{54\left(x+\frac{1}{3}\right)}$$

For the pole at $x = -\frac{1}{3}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{19}{324}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{19}{18} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{18}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{6} - \frac{37}{18x} - \frac{319}{27x^2} - \frac{11831}{81x^3} - \frac{2157901}{972x^4} - \frac{110035199}{2916x^5} - \frac{1501983319}{2187x^6} - \frac{85889060456}{6561x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 24x - 6}{36x^2 + 24x + 4} \\ &= Q + \frac{R}{36x^2 + 24x + 4} \\ &= \left(\frac{1}{36}\right) + \left(\frac{-\frac{74x}{3} - \frac{55}{9}}{36x^2 + 24x + 4}\right) \\ &= \frac{1}{36} + \frac{-\frac{74x}{3} - \frac{55}{9}}{36x^2 + 24x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is $-\frac{74}{3}$. Dividing this by leading coefficient in t which is 36 gives $-\frac{37}{54}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{37}{54}\right) - (0) \\ &= -\frac{37}{54} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{6} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{37}{54}}{\frac{1}{6}} - 0\right) &&= -\frac{37}{18} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{37}{54}}{\frac{1}{6}} - 0\right) &&= \frac{37}{18} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 24x - 6}{4(1+3x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-\frac{1}{3}$	2	0	$\frac{19}{18}$	$-\frac{1}{18}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{6}$	$-\frac{37}{18}$	$\frac{37}{18}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{37}{18}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\ &= \frac{37}{18} - \left(\frac{19}{18}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{19}{18\left(x+\frac{1}{3}\right)} + (-)\left(\frac{1}{6}\right) \\
&= \frac{19}{18\left(x+\frac{1}{3}\right)} - \frac{1}{6} \\
&= -\frac{-6+x}{2\,(1+3x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{19}{18\left(x+\frac{1}{3}\right)} - \frac{1}{6}\right)(1) + \left(\left(-\frac{19}{18\left(x+\frac{1}{3}\right)^2}\right) + \left(\frac{19}{18\left(x+\frac{1}{3}\right)} - \frac{1}{6}\right)^2 - \left(\frac{x^2-24x-6}{4\,(1+3x)^2}\right)\right) = 0$$

$$\frac{a_0+6}{1+3x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -6\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = -6 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\,dx} \\
&= (-6+x)\,\mathrm{e}^{\int\left(\frac{19}{18\left(x+\frac{1}{3}\right)} - \frac{1}{6}\right)dx} \\
&= (-6+x)\,\mathrm{e}^{-\frac{x}{6} + \frac{19\ln(1+3x)}{18}} \\
&= (-6+x)\,(1+3x)^{19/18}\,\mathrm{e}^{-\frac{x}{6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{1+3x}\,dx} \\
&= z_1 e^{-\frac{x}{6}+\frac{\ln(1+3x)}{18}} \\
&= z_1\left((1+3x)^{1/18}\,\mathrm{e}^{-\frac{x}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (1+3x)^{10/9}\,\mathrm{e}^{-\frac{x}{3}}(-6+x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1+3x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x}{3}+\frac{\ln(1+3x)}{9}}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{x}{3}+\frac{\ln(1+3x)}{9}}\,\mathrm{e}^{\frac{2x}{3}}}{(1+3x)^{20/9}\,(-6+x)^2}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left((1+3x)^{10/9}\,\mathrm{e}^{-\frac{x}{3}}(-6+x)\right) \\
&\quad + c_2\left((1+3x)^{10/9}\,\mathrm{e}^{-\frac{x}{3}}(-6+x)\left(\int \frac{\mathrm{e}^{-\frac{x}{3}+\frac{\ln(1+3x)}{9}}\,\mathrm{e}^{\frac{2x}{3}}}{(1+3x)^{20/9}\,(-6+x)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.68.2 Maple step by step solution

Let's solve

$(1+3x)\left(\frac{d}{dx}y'\right)+xy'+2y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{2y}{1+3x}-\frac{xy'}{1+3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{xy'}{1+3x}+\frac{2y}{1+3x}=0$

□ Check to see if $x_0=-\frac{1}{3}$ is a regular singular point

- ∘ Define functions

  $\left[P_2(x)=\frac{x}{1+3x}, P_3(x)=\frac{2}{1+3x}\right]$

- ∘ $\left(x+\frac{1}{3}\right)\cdot P_2(x)$ is analytic at $x=-\frac{1}{3}$

  $\left(\left(x+\frac{1}{3}\right)\cdot P_2(x)\right)\Big|_{x=-\frac{1}{3}}=-\frac{1}{9}$

- ∘ $\left(x+\frac{1}{3}\right)^2\cdot P_3(x)$ is analytic at $x=-\frac{1}{3}$

  $\left(\left(x+\frac{1}{3}\right)^2\cdot P_3(x)\right)\Big|_{x=-\frac{1}{3}}=0$

- ∘ $x=-\frac{1}{3}$is a regular singular point

Check to see if $x_0=-\frac{1}{3}$ is a regular singular point

$x_0=-\frac{1}{3}$

- Multiply by denominators

$(1+3x)\left(\frac{d}{dx}y'\right)+xy'+2y=0$

- Change variables using $x=u-\frac{1}{3}$ so that the regular singular point is at $u=0$

$3u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+\left(u-\frac{1}{3}\right)\left(\frac{d}{du}y(u)\right)+2y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ∘ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^{m}\cdot \left(\frac{d}{du}y \left(u \right)\right)=\sum_{k =-1+m}^{\infty}a_{k +1-m} \left(k +1-m +r \right) u^{k +r}$

- Convert $u \cdot \left(\frac{d}{du}\frac{d}{du}y \left(u \right)\right)$ to series expansion

  $u \cdot \left(\frac{d}{du}\frac{d}{du}y \left(u \right)\right)=\sum_{k =0}^{\infty}a_{k} \left(k +r \right) \left(k +r -1\right) u^{k +r -1}$

- Shift index using $k->k+1$

  $u \cdot \left(\frac{d}{du}\frac{d}{du}y \left(u \right)\right)=\sum_{k =-1}^{\infty}a_{k +1} \left(k +1+r \right) \left(k +r \right) u^{k +r}$

  Rewrite ODE with series expansions

  $\frac{a_{0} r \left(-10+9 r \right) u^{-1+r}}{3}+\left(\sum_{k =0}^{\infty}\left(\frac{a_{k +1} \left(k +1+r \right) \left(9 k -1+9 r \right)}{3}+a_{k} \left(k +r +2\right)\right) u^{k +r}\right)=0$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $\frac{r \left(-10+9 r \right)}{3}=0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{10}{9}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $3 \left(k +1+r \right) \left(k -\frac{1}{9}+r \right) a_{k +1}+a_{k} \left(k +r +2\right)=0$

- Recursion relation that defines series solution to ODE

  $a_{k +1}=-\frac{3 a_{k} \left(k +r +2\right)}{\left(k +1+r \right) \left(9 k -1+9 r \right)}$

- Recursion relation for $r =0$

  $a_{k +1}=-\frac{3 a_{k} \left(k +2\right)}{\left(k +1\right) \left(9 k -1\right)}$

- Solution for $r =0$

  $\left[y \left(u \right)=\sum_{k =0}^{\infty}a_{k} u^{k}, a_{k +1}=-\frac{3 a_{k} \left(k +2\right)}{\left(k +1\right) \left(9 k -1\right)}\right]$

- Revert the change of variables $u =x +\frac{1}{3}$

  $\left[y=\sum_{k =0}^{\infty}a_{k} \left(x +\frac{1}{3}\right)^{k}, a_{k +1}=-\frac{3 a_{k} \left(k +2\right)}{\left(k +1\right) \left(9 k -1\right)}\right]$

- Recursion relation for $r =\frac{10}{9}$

  $a_{k +1}=-\frac{3 a_{k} \left(k +\frac{28}{9}\right)}{\left(k +\frac{19}{9}\right) \left(9 k +9\right)}$

- Solution for $r =\frac{10}{9}$

  $\left[y \left(u \right)=\sum_{k =0}^{\infty}a_{k} u^{k +\frac{10}{9}}, a_{k +1}=-\frac{3 a_{k} \left(k +\frac{28}{9}\right)}{\left(k +\frac{19}{9}\right) \left(9 k +9\right)}\right]$

- Revert the change of variables $u = x + \frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x + \frac{1}{3}\right)^{k+\frac{10}{9}}, a_{k+1} = -\frac{3a_k \left(k+\frac{28}{9}\right)}{\left(k+\frac{19}{9}\right)(9k+9)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k \left(x + \frac{1}{3}\right)^{k}\right) + \left(\sum_{k=0}^{\infty} b_k \left(x + \frac{1}{3}\right)^{k+\frac{10}{9}}\right), a_{k+1} = -\frac{3a_k(k+2)}{(k+1)(9k-1)}, b_{k+1} = -\frac{3b_k \left(k+\frac{28}{9}\right)}{\left(k+\frac{19}{9}\right)(9k+9)}\right]$$

1.69.1 Solved as second order ode using Kovacic algorithm

Time used: 0.829 (sec)

Writing the ode as

$$\left(3x^2+x+1\right)y''+(2+15x)\,y'+12y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=3x^2+x+1\\B&=2+15x\\C&=12\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-9x^2 - 12x - 18}{4\left(3x^2 + x + 1\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -9x^2 - 12x - 18 \\
t &= 4\left(3x^2 + x + 1\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-9x^2 - 12x - 18}{4\left(3x^2 + x + 1\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 123: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\&= 4 - 2\\&= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(3x^2 + x + 1)^2$. There is a pole at $x = -\frac{1}{6} + \frac{i\sqrt{11}}{6}$ of order 2. There is a pole at $x = -\frac{1}{6} - \frac{i\sqrt{11}}{6}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{\frac{27}{88} + \frac{3i\sqrt{11}}{88}}{\left(x + \frac{1}{6} - \frac{i\sqrt{11}}{6}\right)^2} + \frac{\frac{27}{88} - \frac{3i\sqrt{11}}{88}}{\left(x + \frac{1}{6} + \frac{i\sqrt{11}}{6}\right)^2} + \frac{57i\sqrt{11}}{242\left(x + \frac{1}{6} - \frac{i\sqrt{11}}{6}\right)} - \frac{57i\sqrt{11}}{242\left(x + \frac{1}{6} + \frac{i\sqrt{11}}{6}\right)}$$

For the pole at $x = -\frac{1}{6} + \frac{i\sqrt{11}}{6}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{6}-\frac{i\sqrt{11}}{6}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{27}{88} + \frac{3i\sqrt{11}}{88}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{1078 + 66i\sqrt{11}}}{44}\\\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{1078 + 66i\sqrt{11}}}{44}\end{aligned}$$

For the pole at $x = -\frac{1}{6} - \frac{i\sqrt{11}}{6}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{6}+\frac{i\sqrt{11}}{6}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{27}{88} - \frac{3i\sqrt{11}}{88}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{1078 - 66i\sqrt{11}}}{44}\\\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{1078 - 66i\sqrt{11}}}{44}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-9x^2 - 12x - 18}{4\left(3x^2 + x + 1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-9x^2 - 12x - 18}{4\left(3x^2 + x + 1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{6} + \frac{i\sqrt{11}}{6}$	2	0	$\frac{1}{2} + \frac{\sqrt{1078+66i\sqrt{11}}}{44}$	$\frac{1}{2} - \frac{\sqrt{1078+66i\sqrt{11}}}{44}$
$-\frac{1}{6} - \frac{i\sqrt{11}}{6}$	2	0	$\frac{1}{2} + \frac{\sqrt{1078-66i\sqrt{11}}}{44}$	$\frac{1}{2} - \frac{\sqrt{1078-66i\sqrt{11}}}{44}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2} - \frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x + \frac{1}{6} - \frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2} - \frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x + \frac{1}{6} + \frac{i\sqrt{11}}{6}} + (-)(0) \\
&= \frac{\frac{1}{2} - \frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x + \frac{1}{6} - \frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2} - \frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x + \frac{1}{6} + \frac{i\sqrt{11}}{6}} \\
&= -\frac{3x}{6x^2 + 2x + 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x + \frac{1}{6} - \frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2} - \frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x + \frac{1}{6} + \frac{i\sqrt{11}}{6}} \right)(1) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{1078+66i\sqrt{11}}}{44}}{\left(x + \frac{1}{6} - \frac{i\sqrt{11}}{6}\right)^2} - \frac{\frac{1}{2} - \frac{\sqrt{1078-66i\sqrt{11}}}{44}}{\left(x + \frac{1}{6} + \frac{i\sqrt{11}}{6}\right)^2} \right) + \left(\frac{1}{2}\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, \mathrm{e}^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x + \frac{1}{6} - \frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2} - \frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x + \frac{1}{6} + \frac{i\sqrt{11}}{6}} \right) dx} \\
&= (x)\, \mathrm{e}^{-\frac{\ln\left(36x^2+12x+12\right)}{4} + \frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}} \\
&= \frac{x\sqrt{2}\, 3^{3/4} \mathrm{e}^{\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}}}{6\, (3x^2 + x + 1)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2+15x}{3x^2+x+1} \, dx} \\
&= z_1 e^{-\frac{5\ln\left(3x^2+x+1\right)}{4} + \frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}}}{(3x^2 + x + 1)^{5/4}} \right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^{\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} x\sqrt{2}\, 3^{3/4}}{6\, (3x^2 + x + 1)^{3/2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2+15x}{3x^2+x+1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{5\ln\left(3x^2+x+1\right)}{2} + \frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}}}{(y_1)^2} \, dx
\end{aligned}
$$

$$= y_1 \left(\int \frac{2\,\mathrm{e}^{-\frac{5\ln\left(3x^2+x+1\right)}{2}+\frac{\sqrt{11}\,\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} \left(3x^2+x+1\right)^3 \mathrm{e}^{-\frac{2\sqrt{11}\,\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} \sqrt{3}}{x^2} dx \right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{\mathrm{e}^{\frac{\sqrt{11}\,\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} x\sqrt{2}\,3^{3/4}}{6\left(3x^2+x+1\right)^{3/2}} \right)$$
$$+ c_2 \left(\frac{\mathrm{e}^{\frac{\sqrt{11}\,\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} x\sqrt{2}\,3^{3/4}}{6\left(3x^2+x+1\right)^{3/2}} \left(\int \frac{2\,\mathrm{e}^{-\frac{5\ln\left(3x^2+x+1\right)}{2}+\frac{\sqrt{11}\,\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} \left(3x^2+x+1\right)^3 \mathrm{e}^{-\frac{2\sqrt{11}\,\arctan\left(\frac{(6x-}{}\right)}{11}}}{x^2} \right.\right.$$

Will add steps showing solving for IC soon.

1.69.2 Maple step by step solution

Let's solve

$\left(3x^2+x+1\right)\left(\frac{d}{dx}y'\right) + (2+15x)\,y' + 12y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{12y}{3x^2+x+1} - \frac{(2+15x)y'}{3x^2+x+1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(2+15x)y'}{3x^2+x+1} + \frac{12y}{3x^2+x+1} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{2+15x}{3x^2+x+1}, P_3(x) = \frac{12}{3x^2+x+1}\right]$

  ◦ $\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)\cdot P_2(x)$ is analytic at $x = -\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$

  $\left(\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)\cdot P_2(x)\right)\bigg|_{x=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}} = 0$

  ◦ $\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)^2\cdot P_3(x)$ is analytic at $x = -\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$

$$\left(\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)^2\cdot P_3(x)\right)\bigg|_{x=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}}=0$$

- $x=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$ is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$

- Multiply by denominators

  $(3x^2+x+1)\left(\frac{d}{dx}y'\right)+(2+15x)\,y'+12y=0$

- Change variables using $x=u-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$ so that the regular singular point is at $u=0$

  $(3u^2-\mathrm{I}u\sqrt{11})\left(\frac{d}{du}\frac{d}{du}y(u)\right)+\left(-\frac{1}{2}+15u-\frac{5\,\mathrm{I}\sqrt{11}}{2}\right)\left(\frac{d}{du}y(u)\right)+12y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m=1..2$

    $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $\frac{\mathrm{I}\sqrt{11}\,r\left(\mathrm{I}\sqrt{11}-33-22r\right)a_0u^{-1+r}}{22}+\left(\sum_{k=0}^{\infty}\left(\frac{\mathrm{I}\sqrt{11}\,(k+1+r)\left(\mathrm{I}\sqrt{11}-22k-55-22r\right)a_{k+1}}{22}+3a_k(k+r+2)^2\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $\frac{\mathrm{I}}{22}\sqrt{11}\,r\left(\mathrm{I}\sqrt{11}-33-22r\right)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{0,-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right\}$

- Each term in the series must be 0, giving the recursion relation

$$3a_k(k+r+2)^2-(k+1+r)\,a_{k+1}\left(\frac{1}{2}+\mathrm{I}\left(k+r+\frac{5}{2}\right)\sqrt{11}\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{6a_k\left(k^2+2kr+r^2+4k+4r+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+4\,\mathrm{I}kr\sqrt{11}+2\,\mathrm{I}\sqrt{11}\,r^2+7\,\mathrm{I}k\sqrt{11}+7\,\mathrm{I}r\sqrt{11}+5\,\mathrm{I}\sqrt{11}+k+r+1}$$

- Recursion relation for $r=0$

$$a_{k+1}=\frac{6a_k\left(k^2+4k+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+1+7\,\mathrm{I}k\sqrt{11}+5\,\mathrm{I}\sqrt{11}+k}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=\frac{6a_k\left(k^2+4k+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+1+7\,\mathrm{I}k\sqrt{11}+5\,\mathrm{I}\sqrt{11}+k}\right]$$

- Revert the change of variables $u=x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}$

$$\left[y=\sum_{k=0}^{\infty}a_k\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)^k, a_{k+1}=\frac{6a_k\left(k^2+4k+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+1+7\,\mathrm{I}k\sqrt{11}+5\,\mathrm{I}\sqrt{11}+k}\right]$$

- Recursion relation for $r=-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}$

$$a_{k+1}=\frac{6a_k\left(k^2+2k\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)+\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)^2+4k-2+\frac{2\,\mathrm{I}\sqrt{11}}{11}\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+4\,\mathrm{I}k\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)\sqrt{11}+2\,\mathrm{I}\sqrt{11}\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)^2+7\,\mathrm{I}k\sqrt{11}+7\,\mathrm{I}\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)\sqrt{11}+\frac{111\,\mathrm{I}\sqrt{11}}{22}+k-\frac{1}{2}}$$

- Solution for $r=-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}}, a_{k+1}=\frac{6a_k\left(k^2+2k\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)+\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)^2+4k-2+\frac{2\,\mathrm{I}\sqrt{11}}{11}\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+4\,\mathrm{I}k\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)\sqrt{11}+2\,\mathrm{I}\sqrt{11}\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)^2+7\,\mathrm{I}k\sqrt{11}+7\,\mathrm{I}\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)\sqrt{11}}$$

- Revert the change of variables $u=x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}$

$$\left[y=\sum_{k=0}^{\infty}a_k\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)^{k-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}}, a_{k+1}=\frac{6a_k\left(k^2+2k\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)+\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)^2+4k-2\right.}{2\,\mathrm{I}\sqrt{11}\,k^2+4\,\mathrm{I}k\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)\sqrt{11}+2\,\mathrm{I}\sqrt{11}\left(-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right)^2+7\,\mathrm{I}k\sqrt{11}+7\,\mathrm{I}\left(\right.}$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)^k\right)+\left(\sum_{k=0}^{\infty}b_k\left(x+\frac{1}{6}+\frac{\mathrm{I}\sqrt{11}}{6}\right)^{k-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}}\right), a_{k+1}=\frac{6a_k\left(k^2+4k+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+1+7\,\mathrm{I}k\sqrt{11}+5\,\mathrm{I}\right.}$$

1.70 problem 72

Internal problem ID [8208]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 72
Date solved : `Monday, October 21, 2024 at 05:03:23 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2+x)\,y''+(1+x)\,y'+3y=0$$

1.70.1 Solved as second order ode using Kovacic algorithm

Time used: 0.393 (sec)

Writing the ode as

$$(2+x)\,y''+(1+x)\,y'+3y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2+x\\B&=1+x\\C&=3\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 10x - 21}{4\left(2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 10x - 21$$
$$t = 4(2+x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 10x - 21}{4\left(2+x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 125: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2+x)^2$. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{7}{2(2+x)} + \frac{3}{4(2+x)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{7}{2x} - \frac{9}{2x^2} - \frac{97}{2x^3} - \frac{1291}{4x^4} - \frac{11103}{4x^5} - \frac{98061}{4x^6} - \frac{913053}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 10x - 21}{4x^2 + 16x + 16} \\ &= Q + \frac{R}{4x^2 + 16x + 16} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-14x - 25}{4x^2 + 16x + 16}\right) \\ &= \frac{1}{4} + \frac{-14x - 25}{4x^2 + 16x + 16}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -14. Dividing this by leading coefficient in t which is 4 gives $-\frac{7}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{7}{2}\right) - (0) \\ &= -\frac{7}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{7}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{7}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{7}{2}}{\frac{1}{2}} - 0\right) &&= \frac{7}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 10x - 21}{4\left(2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{7}{2}$	$\frac{7}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{7}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{7}{2} - \left(\frac{3}{2}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{3}{2\,(2+x)} + (-)\left(\frac{1}{2}\right) \\ &= \frac{3}{2\,(2+x)} - \frac{1}{2} \\ &= -\frac{-1+x}{2\,(2+x)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{3}{2\,(2+x)} - \frac{1}{2}\right)(2x+a_1) + \left(\left(-\frac{3}{2\,(2+x)^2}\right) + \left(\frac{3}{2\,(2+x)} - \frac{1}{2}\right)^2 - \left(\frac{x^2-10x-21}{4\,(2+x)^2}\right)\right) = 0$$

$$\frac{(a_1+4)\,x + 2a_0 + a_1 + 4}{2+x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0, a_1 = -4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 4x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= \left(x^2 - 4x\right) e^{\int \left(\frac{3}{2(2+x)} - \frac{1}{2}\right) dx} \\ &= \left(x^2 - 4x\right) e^{-\frac{x}{2} + \frac{3\ln(2+x)}{2}} \\ &= x(x-4)\,(2+x)^{3/2}\, e^{-\frac{x}{2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1+x}{2+x}\,dx} \\
&= z_1 e^{-\frac{x}{2}+\frac{\ln(2+x)}{2}} \\
&= z_1\left(\sqrt{2+x}\,\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (2+x)^2\,\mathrm{e}^{-x} x(x-4)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1+x}{2+x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x+\ln(2+x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{e}^{x}}{128x} - \frac{\mathrm{e}^{-2}\,\mathrm{Ei}_1(-2-x)}{48} - \frac{\mathrm{e}^{x}}{3456\,(x-4)} - \frac{11\,\mathrm{e}^{x}}{864\,(2+x)} - \frac{\mathrm{e}^{x}}{288\,(2+x)^2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((2+x)^2\,\mathrm{e}^{-x} x(x-4)\right) + c_2\left((2+x)^2\,\mathrm{e}^{-x} x(x-4)\left(-\frac{\mathrm{e}^{x}}{128x} - \frac{\mathrm{e}^{-2}\,\mathrm{Ei}_1(-2-x)}{48}\right.\right. \\
&\qquad \left.\left. - \frac{\mathrm{e}^{x}}{3456\,(x-4)} - \frac{11\,\mathrm{e}^{x}}{864\,(2+x)} - \frac{\mathrm{e}^{x}}{288\,(2+x)^2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.70.2 Maple step by step solution

Let's solve

$(2+x)\left(\frac{d}{dx}y'\right)+(1+x)\,y'+3y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{3y}{2+x}-\frac{(1+x)y'}{2+x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(1+x)y'}{2+x}+\frac{3y}{2+x}=0$

□ Check to see if $x_0=-2$ is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{1+x}{2+x}, P_3(x)=\frac{3}{2+x}\right]$

  - $(2+x)\cdot P_2(x)$ is analytic at $x=-2$

    $\left((2+x)\cdot P_2(x)\right)\Big|_{x=-2}=-1$

  - $(2+x)^2\cdot P_3(x)$ is analytic at $x=-2$

    $\left((2+x)^2\cdot P_3(x)\right)\Big|_{x=-2}=0$

  - $x=-2$is a regular singular point

  Check to see if $x_0=-2$ is a regular singular point

  $x_0=-2$

- Multiply by denominators

  $(2+x)\left(\frac{d}{dx}y'\right)+(1+x)\,y'+3y=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

  $u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-1+u)\left(\frac{d}{du}y(u)\right)+3y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

$$u^{m} \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion

  $$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-1}$$

- Shift index using $k->k+1$

  $$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, u^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-2+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+r-1) + a_k(k+r+3)\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{0, 2\}$$

- Each term in the series must be 0, giving the recursion relation

  $$a_{k+1}(k+1+r)\,(k+r-1) + a_k(k+r+3) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = -\frac{a_k(k+r+3)}{(k+1+r)(k+r-1)}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-1)}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 1$

  $$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-1)}$$

- Recursion relation for $r = 2$

  $$a_{k+1} = -\frac{a_k(k+5)}{(k+3)(k+1)}$$

- Solution for $r = 2$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = -\frac{a_k(k+5)}{(k+3)(k+1)}\right]$$

- Revert the change of variables $u = 2+x$

  $$\left[y = \sum_{k=0}^{\infty} a_k(2+x)^{k+2}, a_{k+1} = -\frac{a_k(k+5)}{(k+3)(k+1)}\right]$$

1.71 problem 73

Internal problem ID [8209]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 73
Date solved : `Monday, October 21, 2024 at 05:03:24 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(4+x)\,y''+(2+x)\,y'+2y=0$$

1.71.1 Solved as second order ode using Kovacic algorithm

Time used: 0.326 (sec)

Writing the ode as

$$(4+x)\,y''+(2+x)\,y'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4+x \\ B &= 2+x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x - 24}{4\left(4 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 4x - 24$$
$$t = 4(4 + x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x - 24}{4\left(4 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 127: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 2\\ &= 0\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(4+x)^2$. There is a pole at $x = -4$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{(4+x)^2} - \frac{3}{4+x}$$

For the pole at $x = -4$ let b be the coefficient of $\frac{1}{(4+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\ &= \sum_{i=0}^{0} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{3}{x} + \frac{5}{x^2} - \frac{34}{x^3} + \frac{59}{x^4} - \frac{586}{x^5} + \frac{370}{x^6} - \frac{12484}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x - 24}{4x^2 + 32x + 64} \\ &= Q + \frac{R}{4x^2 + 32x + 64} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-12x - 40}{4x^2 + 32x + 64}\right) \\ &= \frac{1}{4} + \frac{-12x - 40}{4x^2 + 32x + 64} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -12. Dividing this by leading coefficient in t which is 4 gives -3. Now b can be found.

$$\begin{aligned} b &= (-3) - (0) \\ &= -3 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-3}{\frac{1}{2}} - 0\right) &= -3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-3}{\frac{1}{2}} - 0\right) &= 3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x - 24}{4\left(4+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-4	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-3	3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 3$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= 3 - (2) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{2}{4+x} + (-)\left(\frac{1}{2}\right) \\
&= \frac{2}{4+x} - \frac{1}{2} \\
&= -\frac{x}{2\,(4+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{2}{4+x} - \frac{1}{2}\right)(1) + \left(\left(-\frac{2}{(4+x)^2}\right) + \left(\frac{2}{4+x} - \frac{1}{2}\right)^2 - \left(\frac{x^2-4x-24}{4\,(4+x)^2}\right)\right) = 0$$

$$\frac{a_0}{4+x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x)\, e^{\int \left(\frac{2}{4+x} - \frac{1}{2}\right) dx} \\
&= (x)\, e^{-\frac{x}{2} + 2\ln(4+x)} \\
&= x(4+x)^2\, e^{-\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2+x}{4+x}\,dx} \\
&= z_1 e^{-\frac{x}{2}+\ln(4+x)} \\
&= z_1\left((4+x)\,\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (4+x)^3\,\mathrm{e}^{-x} x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2+x}{4+x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x+2\ln(4+x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{e}^{x}}{48\,(4+x)^3} - \frac{5\,\mathrm{e}^{x}}{192\,(4+x)^2} - \frac{29\,\mathrm{e}^{x}}{768\,(4+x)} - \frac{\mathrm{e}^{-4}\,\mathrm{Ei}_1(-4-x)}{24} - \frac{\mathrm{e}^{x}}{256x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((4+x)^3\,\mathrm{e}^{-x} x\right) + c_2\left((4+x)^3\,\mathrm{e}^{-x} x\left(-\frac{\mathrm{e}^{x}}{48\,(4+x)^3} - \frac{5\,\mathrm{e}^{x}}{192\,(4+x)^2} - \frac{29\,\mathrm{e}^{x}}{768\,(4+x)} \right.\right. \\
&\qquad \left.\left. - \frac{\mathrm{e}^{-4}\,\mathrm{Ei}_1(-4-x)}{24} - \frac{\mathrm{e}^{x}}{256x}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.71.2 Maple step by step solution

Let's solve

$(4+x)\left(\frac{d}{dx}y'\right)+(2+x)\,y'+2y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{2y}{4+x}-\frac{(2+x)y'}{4+x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{(2+x)y'}{4+x}+\frac{2y}{4+x}=0$

☐ Check to see if $x_0=-4$ is a regular singular point

- ○ Define functions

$\left[P_2(x)=\frac{2+x}{4+x}, P_3(x)=\frac{2}{4+x}\right]$

- ○ $(4+x)\cdot P_2(x)$ is analytic at $x=-4$

$\left((4+x)\cdot P_2(x)\right)\bigg|_{x=-4}=-2$

- ○ $(4+x)^2\cdot P_3(x)$ is analytic at $x=-4$

$\left((4+x)^2\cdot P_3(x)\right)\bigg|_{x=-4}=0$

- ○ $x=-4$is a regular singular point

Check to see if $x_0=-4$ is a regular singular point

$x_0=-4$

- Multiply by denominators

$(4+x)\left(\frac{d}{dx}y'\right)+(2+x)\,y'+2y=0$

- Change variables using $x=u-4$ so that the regular singular point is at $u=0$

$u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-2+u)\left(\frac{d}{du}y(u)\right)+2y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-1}$$

- Shift index using $k- >k+1$

$$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-3+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k-2+r) + a_k(k+r+2)\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-3+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 3\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(k-2+r) + a_k(k+r+2) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k(k+r+2)}{(k+1+r)(k-2+r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{a_k(k+2)}{(k+1)(k-2)}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 2$

$$a_{k+1} = -\frac{a_k(k+2)}{(k+1)(k-2)}$$

- Recursion relation for $r = 3$

$$a_{k+1} = -\frac{a_k(k+5)}{(k+4)(k+1)}$$

- Solution for $r = 3$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+3}, a_{k+1} = -\frac{a_k(k+5)}{(k+4)(k+1)}\right]$$

- Revert the change of variables $u = 4 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k(4+x)^{k+3}, a_{k+1} = -\frac{a_k(k+5)}{(k+4)(k+1)}\right]$$

1.72 problem 74

Internal problem ID [8210]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 74
Date solved : `Monday, October 21, 2024 at 05:03:25 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2+3x\right)y''+10(1+x)\,y'+8y=0$$

1.72.1 Solved as second order ode using Kovacic algorithm

Time used: 0.326 (sec)

Writing the ode as

$$\left(2x^2+3x\right)y''+(10x+10)\,y'+8y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2+3x \\ B &= 10x+10 \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^2 + 6x + 10}{(2x^2 + 3x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -x^2 + 6x + 10$$
$$t = (2x^2 + 3x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^2 + 6x + 10}{(2x^2 + 3x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 129: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{3}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{36\left(x+\frac{3}{2}\right)^2} + \frac{22}{27\left(x+\frac{3}{2}\right)} - \frac{22}{27x} + \frac{10}{9x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{10}{9}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{3}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{2}{3}\end{aligned}$$

For the pole at $x = -\frac{3}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{3}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading

coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 + 6x + 10}{\left(2x^2 + 3x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 + 6x + 10}{\left(2x^2 + 3x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{3}$	$-\frac{2}{3}$
$-\frac{3}{2}$	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{2}{3x} + \frac{1}{6x+9} + (-)(0) \\
&= -\frac{2}{3x} + \frac{1}{6x+9} \\
&= -\frac{x+2}{x(2x+3)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{2}{3x} + \frac{1}{6x+9}\right)(1) + \left(\left(\frac{2}{3x^2} - \frac{1}{6\left(x+\frac{3}{2}\right)^2}\right) + \left(-\frac{2}{3x} + \frac{1}{6x+9}\right)^2 - \left(\frac{-x^2+6x+10}{(2x^2+3x)^2}\right)\right) = 0
$$

$$
\frac{-4+2a_0}{x(2x+3)} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 2\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + 2
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x+2)\, e^{\int \left(-\frac{2}{3x} + \frac{1}{6x+9}\right) dx} \\
&= (x+2)\, e^{-\frac{2\ln(x)}{3} + \frac{\ln(2x+3)}{6}} \\
&= \frac{(x+2)(2x+3)^{1/6}}{x^{2/3}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{10x+10}{2x^2+3x}\,dx} \\
&= z_1 e^{-\frac{5\ln(x)}{3}-\frac{5\ln(2x+3)}{6}} \\
&= z_1\left(\frac{1}{x^{5/3}\left(2x+3\right)^{5/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x+2}{x^{7/3}\left(2x+3\right)^{2/3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{10x+10}{2x^2+3x}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{10\ln(x)}{3}-\frac{5\ln(2x+3)}{3}}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{10\ln(x)}{3}-\frac{5\ln(2x+3)}{3}}x^{14/3}\left(2x+3\right)^{4/3}}{\left(x+2\right)^2}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x+2}{x^{7/3}\left(2x+3\right)^{2/3}}\right) + c_2\left(\frac{x+2}{x^{7/3}\left(2x+3\right)^{2/3}}\left(\int \frac{\mathrm{e}^{-\frac{10\ln(x)}{3}-\frac{5\ln(2x+3)}{3}}x^{14/3}\left(2x+3\right)^{4/3}}{\left(x+2\right)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.72.2 Maple step by step solution

Let's solve

$(2x^2+3x)\left(\frac{d}{dx}y'\right)+10(1+x)\,y'+8y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{8y}{(2x+3)x}-\frac{10(1+x)y'}{x(2x+3)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{10(1+x)y'}{x(2x+3)}+\frac{8y}{(2x+3)x}=0$

□ Check to see if x_0 is a regular singular point

- ○ $x^2\cdot P_3(x)$ is analytic at $x=0$

$(x^2\cdot P_3(x))\bigg|_{x=0}=0$

- ○ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$x(2x+3)\left(\frac{d}{dx}y'\right)+(10x+10)\,y'+8y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m\cdot y'$ to series expansion for $m=0..1$

$x^m\cdot y'=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

$x^m\cdot y'=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ○ Convert $x^m\cdot\left(\frac{d}{dx}y'\right)$ to series expansion for $m=1..2$

$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$

Rewrite ODE with series expansions

$a_0 r(7+3r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(3k+10+3r) + 2a_k(k+r+2)^2\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(7+3r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{0, -\frac{7}{3}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(3k+10+3r) + 2a_k(k+r+2)^2 = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{2a_k(k+r+2)^2}{(k+1+r)(3k+10+3r)}$
- Recursion relation for $r = 0$

  $a_{k+1} = -\frac{2a_k(k+2)^2}{(k+1)(3k+10)}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{2a_k(k+2)^2}{(k+1)(3k+10)}\right]$
- Recursion relation for $r = -\frac{7}{3}$

  $a_{k+1} = -\frac{2a_k\left(k-\frac{1}{3}\right)^2}{\left(k-\frac{4}{3}\right)(3k+3)}$
- Solution for $r = -\frac{7}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{7}{3}}, a_{k+1} = -\frac{2a_k\left(k-\frac{1}{3}\right)^2}{\left(k-\frac{4}{3}\right)(3k+3)}\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{7}{3}}\right), a_{k+1} = -\frac{2a_k(k+2)^2}{(k+1)(3k+10)}, b_{k+1} = -\frac{2b_k\left(k-\frac{1}{3}\right)^2}{\left(k-\frac{4}{3}\right)(3k+3)}\right]$

1.73 problem 75

Internal problem ID [8211]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 75
Date solved : `Monday, October 21, 2024 at 05:03:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - (6 - 7x)\, y' + 8y = 0$$

1.73.1 Solved as second order ode using Kovacic algorithm

Time used: 0.316 (sec)

Writing the ode as

$$x^2y'' + (-6 + 7x)\, y' + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -6 + 7x \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^2 - 60x + 36}{4x^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2 - 60x + 36 \\ t &= 4x^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^2 - 60x + 36}{4x^4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 131: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = -\frac{15}{x^3} + \frac{9}{x^4} + \frac{3}{4x^2}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{3}{x^2} - \frac{5}{2x} - \frac{11}{12} - \frac{55x}{72} - \frac{671x^2}{864} - \frac{4565x^3}{5184} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{3}{x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = 3$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be -15. Therefore

$$\begin{aligned} b &= (-15) - (0) \\ &= -15 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{3}{x^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) &= \frac{1}{2}\left(\frac{-15}{3} + 2\right) &= -\frac{3}{2} \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) &= \frac{1}{2}\left(-\frac{-15}{3} + 2\right) &= \frac{7}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 - 60x + 36}{4x^4}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x^2 - 60x + 36}{4x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{3}{x^2}$	$-\frac{3}{2}$	$\frac{7}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= -\frac{1}{2} - \left(-\frac{3}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{3}{x^2} - \frac{3}{2x} + (-)\,(0) \\
&= \frac{3}{x^2} - \frac{3}{2x} \\
&= -\frac{3(-2+x)}{2x^2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{3}{x^2}-\frac{3}{2x}\right)(1)+\left(\left(-\frac{6}{x^3}+\frac{3}{2x^2}\right)+\left(\frac{3}{x^2}-\frac{3}{2x}\right)^2-\left(\frac{3x^2-60x+36}{4x^4}\right)\right)=0$$
$$\frac{6+3a_0}{x^2}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=-2\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=-2+x$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= (-2+x)\,e^{\int \left(\frac{3}{x^2}-\frac{3}{2x}\right)dx} \\
&= (-2+x)\,e^{-\frac{3}{x}-\frac{3\ln(x)}{2}} \\
&= \frac{(-2+x)\,e^{-\frac{3}{x}}}{x^{3/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6+7x}{x^2}\, dx} \\
&= z_1 e^{-\frac{3}{x}-\frac{7\ln(x)}{2}} \\
&= z_1\left(\frac{e^{-\frac{3}{x}}}{x^{7/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{e^{-\frac{6}{x}}(-2+x)}{x^5}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6+7x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{6}{x}-7\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(7x\,\mathrm{e}^{\frac{6}{x}} + 54\,\mathrm{Ei}_1\left(-\frac{6}{x}\right) + \frac{12\,\mathrm{e}^{\frac{6}{x}}}{\frac{6}{x}-3} + \frac{x^2\mathrm{e}^{\frac{6}{x}}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{-\frac{6}{x}}(-2+x)}{x^5}\right) + c_2 \left(\frac{\mathrm{e}^{-\frac{6}{x}}(-2+x)}{x^5}\left(7x\,\mathrm{e}^{\frac{6}{x}} + 54\,\mathrm{Ei}_1\left(-\frac{6}{x}\right) + \frac{12\,\mathrm{e}^{\frac{6}{x}}}{\frac{6}{x}-3} + \frac{x^2\mathrm{e}^{\frac{6}{x}}}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Solve

$$\left(2x^2+x+1\right)y''+(1+7x)\,y'+2y=0$$

1.74.1 Solved as second order ode using Kovacic algorithm

Time used: 1.066 (sec)

Writing the ode as

$$\left(2x^2+x+1\right)y''+(1+7x)\,y'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2+x+1 \\ B &= 1+7x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5x^2 - 2x + 5}{4\left(2x^2 + x + 1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 5x^2 - 2x + 5$$
$$t = 4\left(2x^2 + x + 1\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5x^2 - 2x + 5}{4\left(2x^2 + x + 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 132: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + x + 1)^2$. There is a pole at $x = -\frac{1}{4} + \frac{i\sqrt{7}}{4}$ of order 2. There is a pole at $x = -\frac{1}{4} - \frac{i\sqrt{7}}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{-\frac{29}{224} + \frac{9i\sqrt{7}}{224}}{\left(x + \frac{1}{4} - \frac{i\sqrt{7}}{4}\right)^2} + \frac{-\frac{29}{224} - \frac{9i\sqrt{7}}{224}}{\left(x + \frac{1}{4} + \frac{i\sqrt{7}}{4}\right)^2} - \frac{8i\sqrt{7}}{49\left(x + \frac{1}{4} - \frac{i\sqrt{7}}{4}\right)} + \frac{8i\sqrt{7}}{49\left(x + \frac{1}{4} + \frac{i\sqrt{7}}{4}\right)}$$

For the pole at $x = -\frac{1}{4} + \frac{i\sqrt{7}}{4}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{4} - \frac{i\sqrt{7}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{29}{224} + \frac{9i\sqrt{7}}{224}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{3\sqrt{42 + 14i\sqrt{7}}}{56} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{3\sqrt{42 + 14i\sqrt{7}}}{56} \end{aligned}$$

For the pole at $x = -\frac{1}{4} - \frac{i\sqrt{7}}{4}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{4} + \frac{i\sqrt{7}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{29}{224} - \frac{9i\sqrt{7}}{224}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{3\sqrt{42 - 14i\sqrt{7}}}{56} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{3\sqrt{42 - 14i\sqrt{7}}}{56} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5x^2 - 2x + 5}{4\left(2x^2 + x + 1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{5x^2 - 2x + 5}{4\left(2x^2 + x + 1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{4} + \frac{i\sqrt{7}}{4}$	2	0	$\frac{1}{2} + \frac{3\sqrt{42+14i\sqrt{7}}}{56}$	$\frac{1}{2} - \frac{3\sqrt{42+14i\sqrt{7}}}{56}$
$-\frac{1}{4} - \frac{i\sqrt{7}}{4}$	2	0	$\frac{1}{2} + \frac{3\sqrt{42-14i\sqrt{7}}}{56}$	$\frac{1}{2} - \frac{3\sqrt{42-14i\sqrt{7}}}{56}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{5}{4} - \left(\frac{1}{4}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2} - \frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x + \frac{1}{4} - \frac{i\sqrt{7}}{4}} + \frac{\frac{1}{2} - \frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x + \frac{1}{4} + \frac{i\sqrt{7}}{4}} + (0) \\
&= \frac{\frac{1}{2} - \frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x + \frac{1}{4} - \frac{i\sqrt{7}}{4}} + \frac{\frac{1}{2} - \frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x + \frac{1}{4} + \frac{i\sqrt{7}}{4}} \\
&= \frac{x + 1}{4x^2 + 2x + 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x + \frac{1}{4} - \frac{i\sqrt{7}}{4}} + \frac{\frac{1}{2} - \frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x + \frac{1}{4} + \frac{i\sqrt{7}}{4}} \right)(1) + \left(\left(-\frac{\frac{1}{2} - \frac{3\sqrt{42+14i\sqrt{7}}}{56}}{\left(x + \frac{1}{4} - \frac{i\sqrt{7}}{4}\right)^2} - \frac{\frac{1}{2} - \frac{3\sqrt{42-14i\sqrt{7}}}{56}}{\left(x + \frac{1}{4} + \frac{i\sqrt{7}}{4}\right)^2} \right) + \left(\frac{\frac{1}{2} - 3\sqrt{}}{x + \frac{1}{4}} \right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x+1)\, \mathrm{e}^{\int \left(\frac{\frac{1}{2}-\frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x+\frac{1}{4}-\frac{i\sqrt{7}}{4}}+\frac{\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x+\frac{1}{4}+\frac{i\sqrt{7}}{4}}\right)dx} \\
&= (x+1)\, \mathrm{e}^{\frac{\ln\left(16x^2+8x+8\right)}{8}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}} \\
&= (x+1)\, 2^{3/8} \left(2x^2+x+1\right)^{1/8} \mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1+7x}{2x^2+x+1}\, dx} \\
&= z_1 e^{-\frac{7\ln\left(2x^2+x+1\right)}{8}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}}}{\left(2x^2+x+1\right)^{7/8}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (x+1)\, 2^{3/8}}{\left(2x^2+x+1\right)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1+7x}{2x^2+x+1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln\left(2x^2+x+1\right)}{4}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{7\ln\left(2x^2+x+1\right)}{4}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} \left(2x^2+x+1\right)^{3/2} \mathrm{e}^{-\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{7}}\, 2^{1/4}}{2\,(x+1)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (x+1)\, 2^{3/8}}{(2x^2+x+1)^{3/4}} \right) \\
&\quad + c_2 \left(\frac{\mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (x+1)\, 2^{3/8}}{(2x^2+x+1)^{3/4}} \left(\int \frac{\mathrm{e}^{-\frac{7\ln\left(2x^2+x+1\right)}{4}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (2x^2+x+1)^{3/2}\, \mathrm{e}^{-\frac{3\sqrt{7}\, \arctan\left(\frac{(4x}{7}}}{2\,(x+1)^2} \right.\right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.74.2 Maple step by step solution

Let's solve

$(2x^2+x+1)\left(\frac{d}{dx}y'\right) + (1+7x)\,y' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{2y}{2x^2+x+1} - \frac{(1+7x)y'}{2x^2+x+1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(1+7x)y'}{2x^2+x+1} + \frac{2y}{2x^2+x+1} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{1+7x}{2x^2+x+1}, P_3(x) = \frac{2}{2x^2+x+1}\right]$

  ◦ $\left(x+\frac{1}{4}+\frac{\mathrm{I}\sqrt{7}}{4}\right)\cdot P_2(x)$ is analytic at $x = -\frac{1}{4}-\frac{\mathrm{I}\sqrt{7}}{4}$

    $\left(\left(x+\frac{1}{4}+\frac{\mathrm{I}\sqrt{7}}{4}\right)\cdot P_2(x)\right)\Big|_{x=-\frac{1}{4}-\frac{\mathrm{I}\sqrt{7}}{4}} = 0$

  ◦ $\left(x+\frac{1}{4}+\frac{\mathrm{I}\sqrt{7}}{4}\right)^2\cdot P_3(x)$ is analytic at $x = -\frac{1}{4}-\frac{\mathrm{I}\sqrt{7}}{4}$

    $\left(\left(x+\frac{1}{4}+\frac{\mathrm{I}\sqrt{7}}{4}\right)^2\cdot P_3(x)\right)\Big|_{x=-\frac{1}{4}-\frac{\mathrm{I}\sqrt{7}}{4}} = 0$

  ◦ $x = -\frac{1}{4}-\frac{\mathrm{I}\sqrt{7}}{4}$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = -\frac{1}{4} - \frac{I\sqrt{7}}{4}$

- Multiply by denominators

  $(2x^2 + x + 1)\left(\frac{d}{dx}y'\right) + (1 + 7x)\,y' + 2y = 0$

- Change variables using $x = u - \frac{1}{4} - \frac{I\sqrt{7}}{4}$ so that the regular singular point is at $u = 0$

  $(2u^2 - Iu\sqrt{7})\left(\frac{d}{du}\frac{d}{du}y(u)\right) + \left(-\frac{3}{4} + 7u - \frac{7\,I\sqrt{7}}{4}\right)\left(\frac{d}{du}y(u)\right) + 2y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k + r)\,u^{k+r-1+m}$

  - Shift index using $k- > k + 1 - m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\,u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

    $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k + r)\,(k + r - 1)\,u^{k+r-2+m}$

  - Shift index using $k- > k + 2 - m$

    $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k + 2 - m + r)\,(k + 1 - m + r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $\frac{I\sqrt{7}\,r\left(3\,I\sqrt{7}-21-28r\right)a_0 u^{-1+r}}{28} + \left(\sum_{k=0}^{\infty}\left(\frac{I\sqrt{7}\,(k+1+r)\left(3\,I\sqrt{7}-28k-49-28r\right)a_{k+1}}{28} + a_k(k + r + 2)\,(2k + 2r + 1)\right)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $\frac{I}{28}\sqrt{7}\,r\left(3\,I\sqrt{7} - 21 - 28r\right) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{3\,I\sqrt{7}}{28} - \frac{3}{4}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-I\left(k + r + \frac{7}{4}\right) a_{k+1}(k + 1 + r)\,\sqrt{7} + \frac{(-3k-3r-3)a_{k+1}}{4} + 2\left(k + r + \frac{1}{2}\right)(k + r + 2)\,a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{4a_k\,(2k^2+4kr+2r^2+5k+5r+2)}{3+4\,I\sqrt{7}\,k^2+8\,I\sqrt{7}\,kr+4\,I\sqrt{7}\,r^2+11\,I\sqrt{7}\,k+11\,I\sqrt{7}\,r+7\,I\sqrt{7}+3k+3r}$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{4a_k(2k^2+5k+2)}{3+4\,\mathrm{I}\sqrt{7}\,k^2+11\,\mathrm{I}\sqrt{7}\,k+7\,\mathrm{I}\sqrt{7}+3k}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{4a_k(2k^2+5k+2)}{3+4\,\mathrm{I}\sqrt{7}\,k^2+11\,\mathrm{I}\sqrt{7}\,k+7\,\mathrm{I}\sqrt{7}+3k}\right]$$

- Revert the change of variables $u = x + \frac{1}{4} + \frac{\mathrm{I}\sqrt{7}}{4}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x + \frac{1}{4} + \frac{\mathrm{I}\sqrt{7}}{4}\right)^k, a_{k+1} = \frac{4a_k(2k^2+5k+2)}{3+4\,\mathrm{I}\sqrt{7}\,k^2+11\,\mathrm{I}\sqrt{7}\,k+7\,\mathrm{I}\sqrt{7}+3k}\right]$$

- Recursion relation for $r = \frac{3\,\mathrm{I}\sqrt{7}}{28} - \frac{3}{4}$

$$a_{k+1} = \frac{4a_k\left(2k^2+4k\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+2\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)^2+5k+\frac{15\,\mathrm{I}\sqrt{7}}{28}-\frac{7}{4}\right)}{\frac{3}{4}+4\,\mathrm{I}\sqrt{7}\,k^2+8\,\mathrm{I}\sqrt{7}\,k\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+4\,\mathrm{I}\sqrt{7}\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)^2+11\,\mathrm{I}\sqrt{7}\,k+11\,\mathrm{I}\sqrt{7}\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+\frac{205\,\mathrm{I}\sqrt{7}}{28}+3k}$$

- Solution for $r = \frac{3\,\mathrm{I}\sqrt{7}}{28} - \frac{3}{4}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}}, a_{k+1} = \frac{4a_k\left(2k^2+4k\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+2\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)^2+5k+\frac{15\,\mathrm{I}\sqrt{7}}{28}-\frac{7}{4}\right)}{\frac{3}{4}+4\,\mathrm{I}\sqrt{7}\,k^2+8\,\mathrm{I}\sqrt{7}\,k\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+4\,\mathrm{I}\sqrt{7}\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)^2+11\,\mathrm{I}\sqrt{7}\,k+11\,\mathrm{I}\sqrt{7}\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+$$

- Revert the change of variables $u = x + \frac{1}{4} + \frac{\mathrm{I}\sqrt{7}}{4}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x + \frac{1}{4} + \frac{\mathrm{I}\sqrt{7}}{4}\right)^{k+\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}}, a_{k+1} = \frac{4a_k\left(2k^2+4k\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+2\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)^2+5k+\frac{15\,\mathrm{I}\sqrt{7}}{28}\right.}{\frac{3}{4}+4\,\mathrm{I}\sqrt{7}\,k^2+8\,\mathrm{I}\sqrt{7}\,k\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)+4\,\mathrm{I}\sqrt{7}\left(\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}\right)^2+11\,\mathrm{I}\sqrt{7}\,k+11\,\mathrm{I}\sqrt{7}}$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k \left(x + \frac{1}{4} + \frac{\mathrm{I}\sqrt{7}}{4}\right)^k\right) + \left(\sum_{k=0}^{\infty} b_k \left(x + \frac{1}{4} + \frac{\mathrm{I}\sqrt{7}}{4}\right)^{k+\frac{3\,\mathrm{I}\sqrt{7}}{28}-\frac{3}{4}}\right), a_{k+1} = \frac{4a_k(2k^2+5k+2)}{3+4\,\mathrm{I}\sqrt{7}\,k^2+11\,\mathrm{I}\sqrt{7}\,k+7\,\mathrm{I}\sqrt{7}}\right.$$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 77
Date solved : `Monday, October 21, 2024 at 05:03:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(3+x)\,y''+(1+2x)\,y'-(2-x)\,y=0$$

1.75.1 Solved as second order ode using Kovacic algorithm

Time used: 0.202 (sec)

Writing the ode as

$$(3+x)\,y''+(1+2x)\,y'+(x-2)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3+x \\ B &= 1+2x \\ C &= x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{35}{4(3+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 35$$
$$t = 4(3+x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{35}{4(3+x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 134: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(3+x)^2$. There is a pole at $x = -3$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{35}{4\left(3+x\right)^2}
$$

For the pole at $x = -3$ let b be the coefficient of $\frac{1}{(3+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{35}{4\left(3+x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{35}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{35}{4 \left(3+x \right)^{2}}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-3	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{5}{2} - \left(-\frac{5}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{5}{2 \left(3+x \right)} + \left(-\right) \left(0\right) \\ &= -\frac{5}{2 \left(3+x \right)} \\ &= -\frac{5}{2 \left(3+x \right)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{2(3+x)}\right)(0) + \left(\left(\frac{5}{2(3+x)^2}\right) + \left(-\frac{5}{2(3+x)}\right)^2 - \left(\frac{35}{4(3+x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{5}{2(3+x)} dx} \\
&= \frac{1}{(3+x)^{5/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1+2x}{3+x} \, dx} \\
&= z_1 e^{-x + \frac{5\ln(3+x)}{2}} \\
&= z_1 \left((3+x)^{5/2} e^{-x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{1+2x}{3+x}\,dx}}{(y_1)^2}\,dx$$
$$= y_1 \int \frac{e^{-2x+5\ln(3+x)}}{(y_1)^2}\,dx$$
$$= y_1 \left(\frac{x(x^5 + 18x^4 + 135x^3 + 540x^2 + 1215x + 1458)\,\mathrm{e}^{-2x+5\ln(3+x)}\mathrm{e}^{2x}}{6\,(3+x)^5}\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x}\left(\frac{x(x^5 + 18x^4 + 135x^3 + 540x^2 + 1215x + 1458)\,\mathrm{e}^{-2x+5\ln(3+x)}\mathrm{e}^{2x}}{6\,(3+x)^5}\right)\right)$$

Will add steps showing solving for IC soon.

1.75.2 Maple step by step solution

Let's solve

$(3+x)\left(\frac{d}{dx}y'\right) + (1+2x)\,y' - (2-x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(x-2)y}{3+x} - \frac{(1+2x)y'}{3+x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(1+2x)y'}{3+x} + \frac{(x-2)y}{3+x} = 0$

□ Check to see if $x_0 = -3$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{1+2x}{3+x}, P_3(x) = \frac{x-2}{3+x}\right]$

  ◦ $(3+x)\cdot P_2(x)$ is analytic at $x = -3$

    $\left((3+x)\cdot P_2(x)\right)\Big|_{x=-3} = -5$

  ◦ $(3+x)^2\cdot P_3(x)$ is analytic at $x = -3$

$\left((3+x)^2 \cdot P_3(x)\right)\Big|_{x=-3} = 0$

- $x=-3$is a regular singular point
  Check to see if $x_0=-3$ is a regular singular point
  $x_0=-3$

- Multiply by denominators
  $(3+x)\left(\frac{d}{dx}y'\right)+(1+2x)\,y'+(x-2)\,y=0$
- Change variables using $x=u-3$ so that the regular singular point is at $u=0$
  $u\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-5+2u)\left(\frac{d}{du}y(u)\right)+(u-5)\,y(u)=0$
- Assume series solution for $y(u)$
  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m=0..1$
  $u^m \cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$
- Shift index using $k->k-m$
  $u^m \cdot y(u)=\sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$
  $u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
- Shift index using $k->k+1-m$
  $u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$
- Convert $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion
  $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-1}$
- Shift index using $k->k+1$
  $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions
  $a_0r(-6+r)\,u^{-1+r}+\left(a_1(1+r)\,(-5+r)+a_0(-5+2r)\right)u^r+\left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+1+r)\,(k-5+r)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-6+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 6\}$
- Each term must be 0

  $a_1(1+r)(-5+r) + a_0(-5+2r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k-5+r) + 2a_k k + 2a_k r - 5a_k + a_{k-1} = 0$
- Shift index using $k- > k+1$

  $a_{k+2}(k+2+r)(k-4+r) + 2a_{k+1}(k+1) + 2ra_{k+1} - 5a_{k+1} + a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2ka_{k+1}+2ra_{k+1}+a_k-3a_{k+1}}{(k+2+r)(k-4+r)}$
- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k-3a_{k+1}}{(k+2)(k-4)}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 4$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k-3a_{k+1}}{(k+2)(k-4)}$
- Recursion relation for $r = 6$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k+9a_{k+1}}{(k+8)(k+2)}$
- Solution for $r = 6$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+6}, a_{k+2} = -\frac{2ka_{k+1}+a_k+9a_{k+1}}{(k+8)(k+2)}, 7a_1 + 7a_0 = 0\right]$
- Revert the change of variables $u = 3 + x$

  $\left[y = \sum_{k=0}^{\infty} a_k (3+x)^{k+6}, a_{k+2} = -\frac{2ka_{k+1}+a_k+9a_{k+1}}{(k+8)(k+2)}, 7a_1 + 7a_0 = 0\right]$

1.76 problem 78

Internal problem ID [8214]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 78
Date solved : `Monday, October 21, 2024 at 05:03:31 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 3xy' + (2x^2 + 4)\, y = 0$$

1.76.1 Solved as second order ode using Kovacic algorithm

Time used: 0.300 (sec)

Writing the ode as

$$y'' + 3xy' + (2x^2 + 4)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3x \\ C &= 2x^2 + 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{x^2 - 10}{4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= x^2 - 10 \\
t &= 4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{x^2}{4} - \frac{5}{2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 136: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{5}{2x} - \frac{25}{4x^3} - \frac{125}{4x^5} - \frac{3125}{16x^7} - \frac{21875}{16x^9} - \frac{328125}{32x^{11}} - \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 10}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{x^2}{4} - \frac{5}{2}\right) + (0) \\
&= \frac{x^2}{4} - \frac{5}{2}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{5}{2}\right) - (0) \\
&= -\frac{5}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= -3 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= 2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{5}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(-\frac{x}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{5}{2}\right)\right) &= 0 \\ a_1 x + 2a_0 + 2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x^2 - 1) \, e^{\int -\frac{x}{2} dx} \\
&= (x^2 - 1) \, e^{-\frac{x^2}{4}} \\
&= (x^2 - 1) \, e^{-\frac{x^2}{4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{3x}{1} \, dx} \\
&= z_1 e^{-\frac{3x^2}{4}} \\
&= z_1 \left(e^{-\frac{3x^2}{4}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = (x^2 - 1) \, e^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{3x^2}{2}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{e^{-\frac{3x^2}{2}} e^{2x^2}}{(x^2 - 1)^2} dx \right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(x^2-1\right) e^{-x^2}\right) + c_2\left(\left(x^2-1\right) e^{-x^2}\left(\int \frac{e^{-\frac{3x^2}{2}} e^{2x^2}}{\left(x^2-1\right)^2} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.76.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + 3xy' + \left(2x^2+4\right) y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ○ Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ○ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

- ○ Convert $\frac{d}{dx}y'$ to series expansion

  $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ○ Shift index using $k- > k + 2$

  $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$$2a_2 + 4a_0 + (6a_3 + 7a_1)\, x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(3k+4) + 2a_{k-2}\right) x^k\right) = 0$$

- The coefficients of each power of x must be 0

  $[2a_2 + 4a_0 = 0, 6a_3 + 7a_1 = 0]$
- Solve for the dependent coefficient(s)

  $\left\{a_2 = -2a_0, a_3 = -\frac{7a_1}{6}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} + 3a_k k + 4a_k + 2a_{k-2} = 0$
- Shift index using $k- >k + 2$

  $\left((k+2)^2 + 3k + 8\right) a_{k+4} + 3a_{k+2}(k+2) + 4a_{k+2} + 2a_k = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{3ka_{k+2}+2a_k+10a_{k+2}}{k^2+7k+12}, a_2 = -2a_0, a_3 = -\frac{7a_1}{6}\right]$

1.77 problem 79

Internal problem ID [8215]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 79
Date solved : `Monday, October 21, 2024 at 05:03:32 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2+4x)\, y'' - 4y' - (6+4x)\, y = 0$$

1.77.1 Solved as second order ode using Kovacic algorithm

Time used: 0.321 (sec)

Writing the ode as

$$(2+4x)\, y'' - 4y' + (-4x-6)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2+4x \\ B &= -4 \\ C &= -4x-6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 + 8x + 6}{(1 + 2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4x^2 + 8x + 6$$
$$t = (1 + 2x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 + 8x + 6}{(1 + 2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 138: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (1+2x)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{3}{4\left(x+\frac{1}{2}\right)^2} + \frac{1}{x+\frac{1}{2}}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{2x} - \frac{1}{4x^3} + \frac{11}{32x^4} - \frac{21}{64x^5} + \frac{15}{64x^6} - \frac{3}{32x^7} - \frac{117}{2048x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 8x + 6}{4x^2 + 4x + 1} \\ &= Q + \frac{R}{4x^2 + 4x + 1} \\ &= (1) + \left(\frac{4x + 5}{4x^2 + 4x + 1}\right) \\ &= 1 + \frac{4x + 5}{4x^2 + 4x + 1} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 1 \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{1}{1} - 0\right) &&= \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{1}{1} - 0\right) &&= -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^2 + 8x + 6}{(1 + 2x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(x + \frac{1}{2}\right)} + (-)(1) \\
&= -\frac{1}{2\left(x + \frac{1}{2}\right)} - 1 \\
&= -\frac{2(x+1)}{1+2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right)(0) + \left(\left(\frac{1}{2\left(x + \frac{1}{2}\right)^2}\right) + \left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right)^2 - \left(\frac{4x^2 + 8x + 6}{(1+2x)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right) dx} \\
&= \frac{e^{-x}}{\sqrt{1+2x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{2+4x} \, dx} \\
&= z_1 e^{\frac{\ln(1+2x)}{2}} \\
&= z_1\left(\sqrt{1+2x}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{2+4x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\ln(1+2x)}}{(y_1)^2} \, dx \\
&= y_1 \left(x \, \mathrm{e}^{2x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(x \, \mathrm{e}^{2x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.77.2 Maple step by step solution

Let's solve

$(2+4x)\left(\frac{d}{dx}y'\right) - 4y' - (6+4x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(2x+3)y}{1+2x} + \frac{2y'}{1+2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{2y'}{1+2x} - \frac{(2x+3)y}{1+2x} = 0$

□ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{2}{1+2x}, P_3(x) = -\frac{2x+3}{1+2x}\right]$

- $\left(x+\frac{1}{2}\right)\cdot P_2(x)$ is analytic at $x=-\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right)\cdot P_2(x)\right)\bigg|_{x=-\frac{1}{2}}=-1$

- $\left(x+\frac{1}{2}\right)^2\cdot P_3(x)$ is analytic at $x=-\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right)^2\cdot P_3(x)\right)\bigg|_{x=-\frac{1}{2}}=0$

- $x=-\frac{1}{2}$is a regular singular point

  Check to see if $x_0=-\frac{1}{2}$ is a regular singular point

  $x_0=-\frac{1}{2}$

- Multiply by denominators

  $(1+2x)\left(\frac{d}{dx}y'\right)-2y'+(-2x-3)\,y=0$

- Change variables using $x=u-\frac{1}{2}$ so that the regular singular point is at $u=0$

  $2u\left(\frac{d}{du}\frac{d}{du}y(u)\right)-2\frac{d}{du}y(u)+(-2u-2)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- Convert $\frac{d}{du}y(u)$ to series expansion

  $\frac{d}{du}y(u)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1}$

- Shift index using $k->k+1$

  $\frac{d}{du}y(u)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,u^{k+r}$

- Convert $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- Shift index using $k->k+1$

$$u \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$2a_0r(-2+r)\,u^{-1+r} + (2a_1(1+r)\,(-1+r) - 2a_0)\,u^r + \left(\sum_{k=1}^{\infty} (2a_{k+1}(k+1+r)\,(k+r-1) - 2a_k$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $2r(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term must be 0
  $2a_1(1+r)\,(-1+r) - 2a_0 = 0$
- Each term in the series must be 0, giving the recursion relation
  $2a_{k+1}(k+1+r)\,(k+r-1) - 2a_k - 2a_{k-1} = 0$
- Shift index using $k- >k+1$
  $2a_{k+2}(k+2+r)\,(k+r) - 2a_{k+1} - 2a_k = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2+r)(k+r)}$
- Recursion relation for $r = 0$
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2)k}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2)k}$
- Recursion relation for $r = 2$
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}$
- Solution for $r = 2$
  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}, 6a_1 - 2a_0 = 0\right]$$
- Revert the change of variables $u = x + \frac{1}{2}$
  $$\left[y = \sum_{k=0}^{\infty} a_k \left(x + \frac{1}{2}\right)^{k+2}, a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}, 6a_1 - 2a_0 = 0\right]$$

1.78 problem 80

Internal problem ID [8216]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 80
Date solved : `Monday, October 21, 2024 at 05:03:33 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - 3xy' + (2x^2 + 5)\,y = 0$$

1.78.1 Solved as second order ode using Kovacic algorithm

Time used: 0.321 (sec)

Writing the ode as

$$y'' - 3xy' + (2x^2 + 5)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3x \\ C &= 2x^2 + 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 26}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 26$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{13}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 140: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{13}{2x} - \frac{169}{4x^3} - \frac{2197}{4x^5} - \frac{142805}{16x^7} - \frac{2599051}{16x^9} - \frac{101362989}{32x^{11}} - \frac{2070701061}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 26}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{x^2}{4} - \frac{13}{2}\right) + (0) \\
&= \frac{x^2}{4} - \frac{13}{2}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{13}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{13}{2}\right) - (0) \\
&= -\frac{13}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{13}{2}}{\frac{1}{2}} - 1\right) &&= -7 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{13}{2}}{\frac{1}{2}} - 1\right) &&= 6
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{13}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-7	6

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 6$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 6 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 6$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^6 + a_5x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(30x^4 + 20x^3a_5 + 12x^2a_4 + 6xa_3 + 2a_2) + 2\left(-\frac{x}{2}\right)(6x^5 + 5x^4a_5 + 4x^3a_4 + 3x^2a_3 + 2xa_2 + a_1) + \left(\left(-\frac{1}{2}\right.\right.$$

$$a_5x^5 + 2(15 + a_4)\,x^4 + (3a_3 + 20a_5)\,x^3 + 4(a_2 + 3a_4)\,x^2 + (5$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -15, a_1 = 0, a_2 = 45, a_3 = 0, a_4 = -15, a_5 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^6 - 15x^4 + 45x^2 - 15$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x^6 - 15x^4 + 45x^2 - 15\right) \mathrm{e}^{\int -\frac{x}{2} dx} \\ &= \left(x^6 - 15x^4 + 45x^2 - 15\right) \mathrm{e}^{-\frac{x^2}{4}} \\ &= \left(x^6 - 15x^4 + 45x^2 - 15\right) \mathrm{e}^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-3x}{1} \, dx} \\ &= z_1 e^{\frac{3x^2}{4}} \\ &= z_1 \left(\mathrm{e}^{\frac{3x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{x^2}{2}} \left(x^6 - 15x^4 + 45x^2 - 15\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\frac{3x^2}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(\int \frac{\mathrm{e}^{\frac{3x^2}{2}} \mathrm{e}^{-x^2}}{\left(x^6 - 15x^4 + 45x^2 - 15\right)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{\frac{x^2}{2}}\left(x^6-15x^4+45x^2-15\right)\right) \\
&\quad + c_2\left(\mathrm{e}^{\frac{x^2}{2}}\left(x^6-15x^4+45x^2-15\right)\left(\int \frac{\mathrm{e}^{\frac{3x^2}{2}}\mathrm{e}^{-x^2}}{\left(x^6-15x^4+45x^2-15\right)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.78.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' - 3xy' + (2x^2+5)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d}{dx}y'$ to series expansion

    $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

    $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

$$2a_2 + 5a_0 + (6a_3 + 2a_1)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) - a_k(3k-5) + 2a_{k-2})\, x^k\right) = 0$$

- The coefficients of each power of x must be 0

  $[2a_2 + 5a_0 = 0, 6a_3 + 2a_1 = 0]$
- Solve for the dependent coefficient(s)

  $\left\{a_2 = -\frac{5a_0}{2}, a_3 = -\frac{a_1}{3}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} - 3a_k k + 5a_k + 2a_{k-2} = 0$
- Shift index using $k- >k+2$

  $\left((k+2)^2 + 3k + 8\right) a_{k+4} - 3a_{k+2}(k+2) + 5a_{k+2} + 2a_k = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = \frac{3k a_{k+2} - 2a_k + a_{k+2}}{k^2+7k+12}, a_2 = -\frac{5a_0}{2}, a_3 = -\frac{a_1}{3}\right]$

1.79 problem 81

Internal problem ID [8217]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 81
Date solved : `Monday, October 21, 2024 at 05:03:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2y'' + 5xy' + \left(2x^2 + 4\right) y = 0$$

1.79.1 Solved as second order ode using Kovacic algorithm

Time used: 0.238 (sec)

Writing the ode as

$$2y'' + 5xy' + \left(2x^2 + 4\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2 \\ B &= 5x \\ C &= 2x^2 + 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9x^2 - 12}{16} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9x^2 - 12$$
$$t = 16$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{9x^2}{16} - \frac{3}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 142: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3x}{4} - \frac{1}{2x} - \frac{1}{6x^3} - \frac{1}{9x^5} - \frac{5}{54x^7} - \frac{7}{81x^9} - \frac{7}{81x^{11}} - \frac{22}{243x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{3x}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{9x^2 - 12}{16} \\ &= Q + \frac{R}{16} \\ &= \left(\frac{9x^2}{16} - \frac{3}{4}\right) + (0) \\ &= \frac{9x^2}{16} - \frac{3}{4} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{3}{4}\right) - (0) \\ &= -\frac{3}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{3x}{4} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{4}}{\frac{3}{4}} - 1\right) &&= -1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{4}}{\frac{3}{4}} - 1\right) &&= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{9x^2}{16} - \frac{3}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{3x}{4}$	-1	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{3x}{4}\right) \\ &= -\frac{3x}{4} \\ &= -\frac{3x}{4} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{3x}{4}\right)(0) + \left(\left(-\frac{3}{4}\right) + \left(-\frac{3x}{4}\right)^2 - \left(\frac{9x^2}{16} - \frac{3}{4}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{3x}{4} dx} \\
&= \mathrm{e}^{-\frac{3x^2}{8}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{5x}{2} dx} \\
&= z_1 e^{-\frac{5x^2}{8}} \\
&= z_1 \left(\mathrm{e}^{-\frac{5x^2}{8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5x}{2} dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{\mathrm{e}^{-\frac{5x^2}{4}}}{(y_1)^2} \, dx \\
&= y_1 \left(-\frac{i\sqrt{\pi}\,\sqrt{3}\,\mathrm{erf}\left(\frac{i\sqrt{3}\,x}{2}\right)}{3} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x^2}\right) + c_2 \left(\mathrm{e}^{-x^2} \left(-\frac{i\sqrt{\pi}\,\sqrt{3}\,\mathrm{erf}\left(\frac{i\sqrt{3}\,x}{2}\right)}{3} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.79.2 Maple step by step solution

Let's solve

$2\frac{d}{dx}y' + 5xy' + (2x^2 + 4)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = (-x^2 - 2)\, y - \frac{5xy'}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{5xy'}{2} + (x^2 + 2)\, y = 0$

- Multiply by denominators

  $2\frac{d}{dx}y' + 5xy' + (2x^2 + 4)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert $\frac{d}{dx}y'$ to series expansion

    $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k + 2$

    $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

$$4a_2 + 4a_0 + (12a_3 + 9a_1)\, x + \left(\sum_{k=2}^{\infty} (2a_{k+2}(k+2)\,(k+1) + a_k(5k+4) + 2a_{k-2})\, x^k\right) = 0$$

- The coefficients of each power of x must be 0

  $[4a_2 + 4a_0 = 0, 12a_3 + 9a_1 = 0]$
- Solve for the dependent coefficient(s)

  $\left\{a_2 = -a_0, a_3 = -\frac{3a_1}{4}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $(2k^2 + 6k + 4)\, a_{k+2} + 5a_k k + 4a_k + 2a_{k-2} = 0$
- Shift index using $k- >k+2$

  $\left(2(k+2)^2 + 6k + 16\right) a_{k+4} + 5a_{k+2}(k+2) + 4a_{k+2} + 2a_k = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{5ka_{k+2}+2a_k+14a_{k+2}}{2(k^2+7k+12)}, a_2 = -a_0, a_3 = -\frac{3a_1}{4}\right]$

1.80 problem 82

Internal problem ID [8218]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 82
Date solved : `Monday, October 21, 2024 at 05:03:35 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 4xy' + (4x^2 + 2)\, y = 0$$

1.80.1 Solved as second order ode using Kovacic algorithm

Time used: 0.097 (sec)

Writing the ode as

$$y'' + 4xy' + (4x^2 + 2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4x \\ C &= 4x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{0}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 0 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 0 \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 144: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{4x}{1} \, dx} \\
&= z_1 e^{-x^2} \\
&= z_1 \left(\mathrm{e}^{-x^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{-2x^2}}{\left(y_1\right)^2} \, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x^2}\right) + c_2\left(\mathrm{e}^{-x^2}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.80.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + 4xy' + (4x^2 + 2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ○ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ○ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

- ○ Convert $\frac{d}{dx}y'$ to series expansion

  $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ○ Shift index using $k- >k + 2$

  $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

Rewrite ODE with series expansions

$2a_2 + 2a_0 + (6a_3 + 6a_1)\, x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)(k+1) + 2a_k(2k+1) + 4a_{k-2}\right) x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 + 2a_0 = 0, 6a_3 + 6a_1 = 0]$
- Solve for the dependent coefficient(s)

  $\{a_2 = -a_0, a_3 = -a_1\}$
- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} + 4a_k k + 2a_k + 4a_{k-2} = 0$
- Shift index using $k- > k + 2$

  $\left((k+2)^2 + 3k + 8\right) a_{k+4} + 4a_{k+2}(k+2) + 2a_{k+2} + 4a_k = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{2(2ka_{k+2}+2a_k+5a_{k+2})}{k^2+7k+12}, a_2 = -a_0, a_3 = -a_1\right]$

1.81 problem 83

Internal problem ID [8219]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 83
Date solved : `Monday, October 21, 2024 at 05:03:36 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0$$

1.81.1 Solved as second order ode using Kovacic algorithm

Time used: 0.102 (sec)

Writing the ode as

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4x \\ C &= 4x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 146: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x}{1}\,dx} \\
&= z_1 e^{-x^2} \\
&= z_1 \left(\mathrm{e}^{-x^2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x^2}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x^2}\right) + c_2\left(\mathrm{e}^{-x^2}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.81.2 Maple step by step solution

Let's solve

$\frac{d}{dx}y' + 4xy' + (4x^2+2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ○ Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ○ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

- ○ Convert $\frac{d}{dx}y'$ to series expansion

  $\frac{d}{dx}y' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ○ Shift index using $k- >k+2$

  $\frac{d}{dx}y' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$2a_2 + 2a_0 + (6a_3 + 6a_1)\,x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + 2a_k(2k+1) + 4a_{k-2}\right) x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 + 2a_0 = 0, 6a_3 + 6a_1 = 0]$
- Solve for the dependent coefficient(s)

  $\{a_2 = -a_0, a_3 = -a_1\}$
- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} + 4a_k k + 2a_k + 4a_{k-2} = 0$
- Shift index using $k- > k+2$

  $\left((k+2)^2 + 3k + 8\right) a_{k+4} + 4a_{k+2}(k+2) + 2a_{k+2} + 4a_k = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{2(2ka_{k+2}+2a_k+5a_{k+2})}{k^2+7k+12}, a_2 = -a_0, a_3 = -a_1\right]$

1.82 problem 84

Internal problem ID [8220]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 84
Date solved : `Monday, October 21, 2024 at 05:03:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(x^2+x+1\right)y''+x\left(11x^2+11x+9\right)y'+\left(7x^2+10x+6\right)y=0$$

1.82.1 Solved as second order ode using Kovacic algorithm

Time used: 1.190 (sec)

Writing the ode as

$$\left(2x^4+2x^3+2x^2\right)y''+\left(11x^3+11x^2+9x\right)y'+\left(7x^2+10x+6\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+2x^3+2x^2 \\ B &= 11x^3+11x^2+9x \\ C &= 7x^2+10x+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{21x^4 + 18x^3 + 27x^2 - 2x - 3}{16\left(x^3 + x^2 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 21x^4 + 18x^3 + 27x^2 - 2x - 3 \\
t &= 16\left(x^3 + x^2 + x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{21x^4 + 18x^3 + 27x^2 - 2x - 3}{16\left(x^3 + x^2 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 148: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 6 - 4 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{-\frac{5}{24} + \frac{i\sqrt{3}}{24}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{5}{24} - \frac{i\sqrt{3}}{24}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{1}{8} - \frac{43i\sqrt{3}}{72}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{-\frac{1}{8} + \frac{43i\sqrt{3}}{72}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} - \frac{3}{16x^2} + \frac{1}{4x}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4}
\end{aligned}
$$

For the pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{24} + \frac{i\sqrt{3}}{24}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{\sqrt{6 + 6i\sqrt{3}}}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{\sqrt{6 + 6i\sqrt{3}}}{12}
\end{aligned}
$$

For the pole at $x=-\frac{1}{2}-\frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{5}{24}-\frac{i\sqrt{3}}{24}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}-\frac{\sqrt{6-6i\sqrt{3}}}{12}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r=\frac{s}{t}=\frac{21x^4+18x^3+27x^2-2x-3}{16\left(x^3+x^2+x\right)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{7}{4} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{21x^4+18x^3+27x^2-2x-3}{16\left(x^3+x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-\frac{1}{2}+\frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}$	$\frac{1}{2}-\frac{\sqrt{6+6i\sqrt{3}}}{12}$
$-\frac{1}{2}-\frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}$	$\frac{1}{2}-\frac{\sqrt{6-6i\sqrt{3}}}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = \frac{7}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+} + \alpha_{c_3}^{+}\right) \\ &= \frac{7}{4} - \left(\frac{7}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{+}}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{4x} + \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}} + (0) \\ &= \frac{1}{4x} + \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}} \\ &= \frac{7x^2+3x+1}{4x\left(x^2+x+1\right)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{4x} + \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}}\right)(0) + \left(\left(-\frac{1}{4x^2} - \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{\left(x+\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)^2} - \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}\right) + \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{4x} + \frac{\frac{1}{2} + \frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} + \frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}}\right) dx} \\
&= 2\left(x^2+x+1\right)^{3/4} \sqrt{2}\, x^{1/4} \mathrm{e}^{-\frac{\sqrt{3}\, \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{11x^3+11x^2+9x}{2x^4+2x^3+2x^2} \, dx} \\
&= z_1 e^{-\frac{9\ln(x)}{4} - \frac{\ln\left(x^2+x+1\right)}{4} - \frac{\sqrt{3}\, \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{\sqrt{3}\, \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}}{x^{9/4} \left(x^2+x+1\right)^{1/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{2\sqrt{x^2+x+1}\, \mathrm{e}^{-\frac{\sqrt{3}\, \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}} \sqrt{2}}{x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{11x^3+11x^2+9x}{2x^4+2x^3+2x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{9\ln(x)}{2} - \frac{\ln\left(x^2+x+1\right)}{2} - \frac{\sqrt{3}\, \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{9\ln(x)}{2} - \frac{\ln\left(x^2+x+1\right)}{2} - \frac{\sqrt{3}\, \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}} x^4 \mathrm{e}^{\frac{2\sqrt{3}\, \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{8x^2+8x+8} dx\right)
\end{aligned}
$$

Therefore the solution is

$$y = c_1y_1 + c_2y_2$$
$$= c_1\left(\frac{2\sqrt{x^2+x+1}\,\mathrm{e}^{-\frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{x^2}\right)$$
$$+c_2\left(\frac{2\sqrt{x^2+x+1}\,\mathrm{e}^{-\frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{x^2}\left(\int \frac{\mathrm{e}^{-\frac{9\ln(x)}{2}-\frac{\ln\left(x^2+x+1\right)}{2}-\frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}x^4\mathrm{e}^{\frac{2\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{8x^2+8x+8}\right.\right.$$

Will add steps showing solving for IC soon.

1.82.2 Maple step by step solution

Let's solve
$2x^2(x^2+x+1)\left(\frac{d}{dx}y'\right) + x(11x^2+11x+9)\,y' + (7x^2+10x+6)\,y = 0$

- Highest derivative means the order of the ODE is 2
$\frac{d}{dx}y'$
- Isolate 2nd derivative
$\frac{d}{dx}y' = -\frac{(7x^2+10x+6)y}{2x^2(x^2+x+1)} - \frac{(11x^2+11x+9)y'}{2x(x^2+x+1)}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
$\frac{d}{dx}y' + \frac{(11x^2+11x+9)y'}{2x(x^2+x+1)} + \frac{(7x^2+10x+6)y}{2x^2(x^2+x+1)} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
  $\left[P_2(x) = \frac{11x^2+11x+9}{2x(x^2+x+1)}, P_3(x) = \frac{7x^2+10x+6}{2x^2(x^2+x+1)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
  $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{9}{2}$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 3$
  - $x = 0$is a regular singular point
  Check to see if x_0 is a regular singular point
  $x_0 = 0$

- Multiply by denominators

  $2x^2(x^2+x+1)\left(\frac{d}{dx}y'\right)+x(11x^2+11x+9)\,y'+(7x^2+10x+6)\,y=0$
- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m=0..2$

    $x^m \cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k->k-m$

    $x^m \cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m=1..3$

    $x^m \cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $x^m \cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m=2..4$

    $x^m \cdot \left(\frac{d}{dx}y'\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k->k+2-m$

    $x^m \cdot \left(\frac{d}{dx}y'\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(3+2r)\,x^r+\left(a_1(3+r)\,(5+2r)+a_0(5+2r)\,(2+r)\right)x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(k+r+2)\,(2k+\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(3+2r)=0$
- Values of r that satisfy the indicial equation

  $r\in\left\{-2,-\frac{3}{2}\right\}$
- Each term must be 0

  $a_1(3+r)\,(5+2r)+a_0(5+2r)\,(2+r)=0$
- Solve for the dependent coefficient(s)

  $a_1=-\frac{(2+r)a_0}{3+r}$

- Each term in the series must be 0, giving the recursion relation

  $2\left(k+r+\frac{3}{2}\right)\left(\left(a_k+a_{k-2}+a_{k-1}\right)k+\left(a_k+a_{k-2}+a_{k-1}\right)r+2a_k-a_{k-2}+a_{k-1}\right)=0$
- Shift index using $k->k+2$

  $2\left(k+\frac{7}{2}+r\right)\left(\left(a_{k+2}+a_k+a_{k+1}\right)(k+2)+\left(a_{k+2}+a_k+a_{k+1}\right)r+2a_{k+2}-a_k+a_{k+1}\right)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{ka_k+ka_{k+1}+ra_k+ra_{k+1}+a_k+3a_{k+1}}{k+4+r}$
- Recursion relation for $r=-2$

  $a_{k+2}=-\frac{ka_k+ka_{k+1}-a_k+a_{k+1}}{k+2}$
- Solution for $r=-2$

  $\left[y=\sum_{k=0}^{\infty}a_kx^{k-2}, a_{k+2}=-\frac{ka_k+ka_{k+1}-a_k+a_{k+1}}{k+2}, a_1=0\right]$
- Recursion relation for $r=-\frac{3}{2}$

  $a_{k+2}=-\frac{ka_k+ka_{k+1}-\frac{1}{2}a_k+\frac{3}{2}a_{k+1}}{k+\frac{5}{2}}$
- Solution for $r=-\frac{3}{2}$

  $\left[y=\sum_{k=0}^{\infty}a_kx^{k-\frac{3}{2}}, a_{k+2}=-\frac{ka_k+ka_{k+1}-\frac{1}{2}a_k+\frac{3}{2}a_{k+1}}{k+\frac{5}{2}}, a_1=-\frac{a_0}{3}\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty}a_kx^{k-2}\right)+\left(\sum_{k=0}^{\infty}b_kx^{k-\frac{3}{2}}\right), a_{k+2}=-\frac{ka_k+ka_{k+1}-a_k+a_{k+1}}{k+2}, a_1=0, b_{k+2}=-\frac{kb_k+kb_{k+1}-\frac{1}{2}b_k+}{k+\frac{5}{2}}\right.$

Solve

$$3x^2y'' + 2x\left(-2x^2 + x + 1\right)y' + \left(-8x^2 + 2x\right)y = 0$$

1.83.1 Solved as second order ode using Kovacic algorithm

Time used: 0.424 (sec)

Writing the ode as

$$3x^2y'' + \left(-4x^3 + 2x^2 + 2x\right)y' + \left(-8x^2 + 2x\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2 \\ B &= -4x^3 + 2x^2 + 2x \\ C &= -8x^2 + 2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4x^4 - 4x^3 + 15x^2 - 4x - 2$$
$$t = 9x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 150: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 9x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{4x^2}{9} - \frac{4x}{9} + \frac{5}{3} - \frac{4}{9x} - \frac{2}{9x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{2}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{2}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{3} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{2x}{3} - \frac{1}{3} + \frac{7}{6x} + \frac{1}{4x^2} - \frac{17}{16x^3} - \frac{31}{32x^4} + \frac{85}{64x^5} + \frac{353}{128x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{2}{3}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= -\frac{1}{3} + \frac{2x}{3} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{9} - \frac{4}{9}x + \frac{4}{9}x^2$$

This shows that the coefficient of 1 in the above is $\frac{1}{9}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2} \\ &= Q + \frac{R}{9x^2} \\ &= \left(\frac{4}{9}x^2 - \frac{4}{9}x + \frac{5}{3}\right) + \left(\frac{-4x - 2}{9x^2}\right) \\ &= \frac{4x^2}{9} - \frac{4x}{9} + \frac{5}{3} + \frac{-4x - 2}{9x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $\frac{5}{3}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{5}{3}\right) - \left(\frac{1}{9}\right) \\ &= \frac{14}{9} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= -\frac{1}{3} + \frac{2x}{3} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{14}{9}}{\frac{2}{3}} - 1\right) &&= \frac{2}{3} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{14}{9}}{\frac{2}{3}} - 1\right) &&= -\frac{5}{3}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{2}{3}$	$\frac{1}{3}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$-\frac{1}{3} + \frac{2x}{3}$	$\frac{2}{3}$	$-\frac{5}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = \frac{2}{3}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{2}{3} - \left(\frac{2}{3}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{2}{3x} + \left(-\frac{1}{3} + \frac{2x}{3}\right) \\
&= \frac{2}{3x} - \frac{1}{3} + \frac{2x}{3} \\
&= \frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}\right)(0) + \left(\left(-\frac{2}{3x^2} + \frac{2}{3}\right) + \left(\frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}\right)^2 - \left(\frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2}\right)\right) = 0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}\right) dx} \\
&= x^{2/3} \mathrm{e}^{\frac{x(x-1)}{3}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-4x^3 + 2x^2 + 2x}{3x^2} \, dx} \\
&= z_1 e^{\frac{x^2}{3} - \frac{x}{3} - \frac{\ln(x)}{3}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x(x-1)}{3}}}{x^{1/3}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = x^{1/3} \mathrm{e}^{\frac{2x(x-1)}{3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^3+2x^2+2x}{3x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{2x^2}{3}-\frac{2x}{3}-\frac{2\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{2x^2}{3}-\frac{2x}{3}-\frac{2\ln(x)}{3}} \mathrm{e}^{-\frac{4x(x-1)}{3}}}{x^{2/3}} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{1/3} \mathrm{e}^{\frac{2x(x-1)}{3}}\right) + c_2 \left(x^{1/3} \mathrm{e}^{\frac{2x(x-1)}{3}} \left(\int \frac{\mathrm{e}^{\frac{2x^2}{3}-\frac{2x}{3}-\frac{2\ln(x)}{3}} \mathrm{e}^{-\frac{4x(x-1)}{3}}}{x^{2/3}} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.83.2 Maple step by step solution

Let's solve

$3x^2 \left(\frac{d}{dx} y'\right) + 2x(-2x^2 + x + 1)\, y' + (-8x^2 + 2x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$
- Isolate 2nd derivative

  $\frac{d}{dx} y' = \frac{2(4x-1)y}{3x} + \frac{2(2x^2-x-1)y'}{3x}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx} y' - \frac{2(2x^2-x-1)y'}{3x} - \frac{2(4x-1)y}{3x} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ○ Shift index using $k- > k + 1$

$x \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

Rewrite ODE with series expansions

$a_0 r(-1+3r)\,x^{-1+r} + \left(a_1(1+r)\,(2+3r) + 2a_0(1+r)\right)x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)\,(3k+2+3r)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-1+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, \frac{1}{3}\right\}$
- Each term must be 0
  $a_1(1+r)\,(2+3r) + 2a_0(1+r) = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+1+r)\,(3ka_{k+1} + 3ra_{k+1} + 2a_k - 4a_{k-1} + 2a_{k+1}) = 0$
- Shift index using $k- >k+1$
  $(k+r+2)\,(3(k+1)\,a_{k+2} + 3ra_{k+2} + 2a_{k+1} - 4a_k + 2a_{k+2}) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{2(-a_{k+1}+2a_k)}{3k+5+3r}$
- Recursion relation for $r = 0$
  $a_{k+2} = \frac{2(-a_{k+1}+2a_k)}{3k+5}$
- Solution for $r = 0$
  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{2(-a_{k+1}+2a_k)}{3k+5}, 2a_1 + 2a_0 = 0\right]$
- Recursion relation for $r = \frac{1}{3}$
  $a_{k+2} = \frac{2(-a_{k+1}+2a_k)}{3k+6}$
- Solution for $r = \frac{1}{3}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = \frac{2(-a_{k+1}+2a_k)}{3k+6}, 4a_1 + \frac{8a_0}{3} = 0\right]$
- Combine solutions and rename parameters
  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = \frac{2(-a_{k+1}+2a_k)}{3k+5}, 2a_1 + 2a_0 = 0, b_{k+2} = \frac{2(-b_{k+1}+2b_k)}{3k+6}, 4b_1 +\right.$

1.84 problem 86

Internal problem ID [8222]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 86
Date solved : `Monday, October 21, 2024 at 05:03:41 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$12x^2(1+x)\,y''+x\left(3x^2+35x+11\right)y'-\left(-5x^2-10x+1\right)y=0$$

1.84.1 Solved as second order ode using Kovacic algorithm

Time used: 0.403 (sec)

Writing the ode as

$$\left(12x^3+12x^2\right)y''+\left(3x^3+35x^2+11x\right)y'+\left(5x^2+10x-1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=12x^3+12x^2\\ B&=3x^3+35x^2+11x\\ C&=5x^2+10x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \\ = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9x^4 - 30x^3 - 197x^2 - 190x - 95}{576 (x^2 + x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9x^4 - 30x^3 - 197x^2 - 190x - 95$$
$$t = 576(x^2 + x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{9x^4 - 30x^3 - 197x^2 - 190x - 95}{576 (x^2 + x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 152: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 576(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{64} - \frac{7}{64\,(1+x)^2} - \frac{95}{576x^2} - \frac{1}{12\,(1+x)}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{95}{576}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{19}{24} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{24} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{8} - \frac{1}{3x} - \frac{29}{24x^2} - \frac{193}{72x^3} - \frac{3017}{216x^4} - \frac{40009}{648x^5} - \frac{642029}{1944x^6} - \frac{10350493}{5832x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{8}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{8}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{64}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading

coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t}\\
&= \frac{9x^4 - 30x^3 - 197x^2 - 190x - 95}{576x^4 + 1152x^3 + 576x^2}\\
&= Q + \frac{R}{576x^4 + 1152x^3 + 576x^2}\\
&= \left(\frac{1}{64}\right) + \left(\frac{-48x^3 - 206x^2 - 190x - 95}{576x^4 + 1152x^3 + 576x^2}\right)\\
&= \frac{1}{64} + \frac{-48x^3 - 206x^2 - 190x - 95}{576x^4 + 1152x^3 + 576x^2}
\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -48. Dividing this by leading coefficient in t which is 576 gives $-\frac{1}{12}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{1}{12}\right) - (0)\\
&= -\frac{1}{12}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{8}\\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{12}}{\frac{1}{8}} - 0\right) &&= -\frac{1}{3}\\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{12}}{\frac{1}{8}} - 0\right) &&= \frac{1}{3}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{9x^4 - 30x^3 - 197x^2 - 190x - 95}{576\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{8}$	$\frac{1}{8}$
0	2	0	$\frac{19}{24}$	$\frac{5}{24}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{8}$	$-\frac{1}{3}$	$\frac{1}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{3}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\ &= \frac{1}{3} - \left(\frac{1}{3}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{8+8x} + \frac{5}{24x} + (-)\left(\frac{1}{8}\right) \\ &= \frac{1}{8+8x} + \frac{5}{24x} - \frac{1}{8} \\ &= \frac{1}{8+8x} + \frac{5}{24x} - \frac{1}{8} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{8+8x} + \frac{5}{24x} - \frac{1}{8}\right)(0) + \left(\left(-\frac{1}{8(1+x)^2} - \frac{5}{24x^2}\right) + \left(\frac{1}{8+8x} + \frac{5}{24x} - \frac{1}{8}\right)^2 - \left(\frac{9x^4 - 30x^3 -}{576}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{8+8x} + \frac{5}{24x} - \frac{1}{8}\right) dx} \\
&= x^{5/24} (1+x)^{1/8} \, \mathrm{e}^{-\frac{x}{8}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{3x^3+35x^2+11x}{12x^3+12x^2} \, dx} \\
&= z_1 e^{-\frac{x}{8} - \frac{11 \ln(x)}{24} - \frac{7 \ln(1+x)}{8}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{8}}}{x^{11/24} (1+x)^{7/8}} \right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^{-\frac{x}{4}}}{x^{1/4} (1+x)^{3/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3+35x^2+11x}{12x^3+12x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{x}{4} - \frac{11 \ln(x)}{12} - \frac{7 \ln(1+x)}{4}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \mathrm{e}^{-\frac{x}{4} - \frac{11 \ln(x)}{12} - \frac{7 \ln(1+x)}{4}} \sqrt{x} \, (1+x)^{3/2} \, \mathrm{e}^{\frac{x}{2}} dx \right)
\end{aligned}
$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$

$$= c_1 \left(\frac{e^{-\frac{x}{4}}}{x^{1/4}\left(1+x\right)^{3/4}}\right) + c_2 \left(\frac{e^{-\frac{x}{4}}}{x^{1/4}\left(1+x\right)^{3/4}}\left(\int e^{-\frac{x}{4}-\frac{11\ln(x)}{12}-\frac{7\ln(1+x)}{4}}\sqrt{x}\,(1+x)^{3/2}\,e^{\frac{x}{2}}dx\right)\right)$$

Will add steps showing solving for IC soon.

1.84.2 Maple step by step solution

Let's solve

$12x^2(1+x)\left(\frac{d}{dx}y'\right) + x(3x^2+35x+11)\,y' - (-5x^2-10x+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(5x^2+10x-1)y}{12x^2(1+x)} - \frac{(3x^2+35x+11)y'}{12x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(3x^2+35x+11)y'}{12x(1+x)} + \frac{(5x^2+10x-1)y}{12x^2(1+x)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{3x^2+35x+11}{12x(1+x)}, P_3(x) = \frac{5x^2+10x-1}{12x^2(1+x)}\right]$

  ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left.\left((1+x)\cdot P_2(x)\right)\right|_{x=-1} = \frac{7}{4}$

  ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left.\left((1+x)^2\cdot P_3(x)\right)\right|_{x=-1} = 0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $12x^2(1+x)\left(\frac{d}{dx}y'\right) + x(3x^2+35x+11)\,y' + (5x^2+10x-1)\,y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(12u^3-24u^2+12u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (3u^3+26u^2-50u+21)\left(\frac{d}{du}y(u)\right) + (5u^2-6)\,y(u) = 0$

- Assume series solution for $y(u)$

$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..2$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k- >k - m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..3$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k- >k + 2 - m$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

Rewrite ODE with series expansions

$3a_0r(3+4r)\, u^{-1+r} + (3a_1(1+r)\,(7+4r) - 2a_0(3+4r)\,(1+3r))\, u^r + (3a_2(2+r)\,(11+4r) - 2$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $3r(3+4r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, -\frac{3}{4}\right\}$

- The coefficients of each power of u must be 0

  $[3a_1(1+r)\,(7+4r) - 2a_0(3+4r)\,(1+3r) = 0, 3a_2(2+r)\,(11+4r) - 2a_1(7+4r)\,(4+3r) + 2a$

- Solve for the dependent coefficient(s)

  $\left\{a_1 = \frac{2a_0(12r^2+13r+3)}{3(4r^2+11r+7)}, a_2 = \frac{2a_0(54r^3+135r^2+101r+24)}{9(4r^3+23r^2+41r+22)}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $12(-2a_k + a_{k-1} + a_{k+1})\, k^2 + (24(-2a_k + a_{k-1} + a_{k+1})\, r - 26a_k + 3a_{k-2} - 10a_{k-1} + 33a_{k+1})\, k +$

- Shift index using $k- >k + 2$

$$12(-2a_{k+2}+a_{k+1}+a_{k+3})\,(k+2)^2+(24(-2a_{k+2}+a_{k+1}+a_{k+3})\,r-26a_{k+2}+3a_k-10a_{k+1}+3$$

- Recursion relation that defines series solution to ODE

$$a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+24kra_{k+1}-48kra_{k+2}+12r^2a_{k+1}-24r^2a_{k+2}+3ka_k+38ka_{k+1}-122ka_{k+2}+3ra_k+38ra_{k+1}-122r}{3(4k^2+8kr+4r^2+27k+27r+45)}$$

- Recursion relation for $r=0$

$$a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+3ka_k+38ka_{k+1}-122ka_{k+2}+5a_k+26a_{k+1}-154a_{k+2}}{3(4k^2+27k+45)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^k,a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+3ka_k+38ka_{k+1}-122ka_{k+2}+5a_k+26a_{k+1}-154a_{k+2}}{3(4k^2+27k+45)},a_1=\frac{2a_0}{7},a_2=\right.$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^k,a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+3ka_k+38ka_{k+1}-122ka_{k+2}+5a_k+26a_{k+1}-154a_{k+2}}{3(4k^2+27k+45)},a_1=\frac{2a_0}{7},\right.$$

- Recursion relation for $r=-\frac{3}{4}$

$$a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+3ka_k+20ka_{k+1}-86ka_{k+2}+\frac{11}{4}a_k+\frac{17}{4}a_{k+1}-76a_{k+2}}{3(4k^2+21k+27)}$$

- Solution for $r=-\frac{3}{4}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k-\frac{3}{4}},a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+3ka_k+20ka_{k+1}-86ka_{k+2}+\frac{11}{4}a_k+\frac{17}{4}a_{k+1}-76a_{k+2}}{3(4k^2+21k+27)},a_1=0,a_2\right.$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^{k-\frac{3}{4}},a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+3ka_k+20ka_{k+1}-86ka_{k+2}+\frac{11}{4}a_k+\frac{17}{4}a_{k+1}-76a_{k+2}}{3(4k^2+21k+27)},a_1=0,\right.$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k(1+x)^k\right)+\left(\sum_{k=0}^{\infty}b_k(1+x)^{k-\frac{3}{4}}\right),a_{k+3}=-\frac{12k^2a_{k+1}-24k^2a_{k+2}+3ka_k+38ka_{k+1}-122ka_{k+2}+5a}{3(4k^2+27k+45)}\right.$$

1.85 problem 87

Internal problem ID [8223]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 87
Date solved : `Monday, October 21, 2024 at 05:03:43 PM`
CAS classification :
`[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, '_with_symmetry_[0,F(x)]`

Solve

$$x^2(10x^2+x+5)\,y''+x(48x^2+3x+4)\,y'+(36x^2+x)\,y=0$$

1.85.1 Solved as second order ode using Kovacic algorithm

Time used: 1.176 (sec)

Writing the ode as

$$(10x^4+x^3+5x^2)\,y''+(48x^3+3x^2+4x)\,y'+(36x^2+x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=10x^4+x^3+5x^2\\B&=48x^3+3x^2+4x\\C&=36x^2+x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-96x^4 - 16x^3 - 97x^2 - 12x - 24}{4\left(10x^3 + x^2 + 5x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -96x^4 - 16x^3 - 97x^2 - 12x - 24 \\
t &= 4\left(10x^3 + x^2 + 5x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-96x^4 - 16x^3 - 97x^2 - 12x - 24}{4\left(10x^3 + x^2 + 5x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 154: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(10x^3 + x^2 + 5x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{20} + \frac{i\sqrt{199}}{20}$ of order 2. There is a pole at $x = -\frac{1}{20} - \frac{i\sqrt{199}}{20}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r = &-\frac{6}{25x^2} - \frac{3}{125x} + \frac{-\frac{1}{19900} - \frac{i\sqrt{199}}{1990}}{\left(x + \frac{1}{20} - \frac{i\sqrt{199}}{20}\right)^2} \\ &+ \frac{-\frac{1}{19900} + \frac{i\sqrt{199}}{1990}}{\left(x + \frac{1}{20} + \frac{i\sqrt{199}}{20}\right)^2} + \frac{\frac{3}{250} - \frac{647i\sqrt{199}}{9900250}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{3}{250} + \frac{647i\sqrt{199}}{9900250}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{6}{25}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{5} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{2}{5} \end{aligned}$$

For the pole at $x = -\frac{1}{20} + \frac{i\sqrt{199}}{20}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{20} - \frac{i\sqrt{199}}{20}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{19900} - \frac{i\sqrt{199}}{1990}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{989826 - 1990i\sqrt{199}}}{1990} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{989826 - 1990i\sqrt{199}}}{1990} \end{aligned}$$

For the pole at $x=-\frac{1}{20}-\frac{i\sqrt{199}}{20}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{20}+\frac{i\sqrt{199}}{20}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{1}{19900}+\frac{i\sqrt{199}}{1990}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}+\frac{\sqrt{989826+1990i\sqrt{199}}}{1990}\\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}-\frac{\sqrt{989826+1990i\sqrt{199}}}{1990}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty=0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r=\frac{s}{t}=\frac{-96x^4-16x^3-97x^2-12x-24}{4\left(10x^3+x^2+5x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{6}{25}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{5}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{2}{5}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-96x^4-16x^3-97x^2-12x-24}{4\left(10x^3+x^2+5x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{5}$	$\frac{2}{5}$
$-\frac{1}{20}+\frac{i\sqrt{199}}{20}$	2	0	$\frac{1}{2}+\frac{\sqrt{989826-1990i\sqrt{199}}}{1990}$	$\frac{1}{2}-\frac{\sqrt{989826-1990i\sqrt{199}}}{1990}$
$-\frac{1}{20}-\frac{i\sqrt{199}}{20}$	2	0	$\frac{1}{2}+\frac{\sqrt{989826+1990i\sqrt{199}}}{1990}$	$\frac{1}{2}-\frac{\sqrt{989826+1990i\sqrt{199}}}{1990}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{5}$	$\frac{2}{5}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{5}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{3}{5} - \left(\frac{3}{5}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}} + (0) \\
&= \frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}} \\
&= \frac{12x^2 + x + 6}{20x^3 + 2x^2 + 10x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}}\right)(0) + \left(\left(-\frac{3}{5x^2} - \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{\left(x + \frac{1}{20} - \frac{i\sqrt{199}}{20}\right)^2} - \right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826 - 1990 i \sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826 + 1990 i \sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}}\right) dx} \\
&= x^{3/5} \mathrm{e}^{-\frac{\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{48x^3 + 3x^2 + 4x}{10x^4 + x^3 + 5x^2} \, dx} \\
&= z_1 e^{-\ln(10x^2 + x + 5) - \frac{\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{2\ln(x)}{5}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{(10x^2 + x + 5)\, x^{2/5}} \right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{1/5} \mathrm{e}^{-\frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{10x^2 + x + 5}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{48x^3 + 3x^2 + 4x}{10x^4 + x^3 + 5x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-2\ln(10x^2 + x + 5) - \frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{4\ln(x)}{5}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-2\ln(10x^2 + x + 5) - \frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{4\ln(x)}{5}} (10x^2 + x + 5)^2 \, \mathrm{e}^{\frac{4\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{x^{2/5}} \, dx \right)
\end{aligned}
$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x^{1/5} \mathrm{e}^{-\frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{10x^2 + x + 5} \right)$$
$$+ c_2 \left(\frac{x^{1/5} \mathrm{e}^{-\frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{10x^2 + x + 5} \left(\int \frac{\mathrm{e}^{-2\ln(10x^2+x+5) - \frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{4\ln(x)}{5}} (10x^2 + x + 5)^2 \mathrm{e}^{\frac{4\sqrt{19}}{}}}{x^{2/5}} \right.\right.$$

Will add steps showing solving for IC soon.

1.85.2 Maple step by step solution

Let's solve

$x^2(10x^2 + x + 5) \left(\frac{d}{dx} y'\right) + x(48x^2 + 3x + 4) y' + (36x^2 + x) y = 0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx} y'$

- Isolate 2nd derivative

$\frac{d}{dx} y' = -\frac{(36x+1)y}{x(10x^2+x+5)} - \frac{(48x^2+3x+4)y'}{x(10x^2+x+5)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx} y' + \frac{(48x^2+3x+4)y'}{x(10x^2+x+5)} + \frac{(36x+1)y}{x(10x^2+x+5)} = 0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x) = \frac{48x^2+3x+4}{x(10x^2+x+5)}, P_3(x) = \frac{36x+1}{x(10x^2+x+5)}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$\left.(x \cdot P_2(x))\right|_{x=0} = \frac{4}{5}$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

- ◦ $x = 0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = 0$

- Multiply by denominators

  $x(10x^2+x+5)\left(\frac{d}{dx}y'\right)+(48x^2+3x+4)\,y'+(36x+1)\,y=0$
- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m\cdot y$ to series expansion for $m=0..1$

    $x^m\cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k->k-m$

    $x^m\cdot y=\sum_{k=m}^{\infty} a_{k-m}x^{k+r}$
  - Convert $x^m\cdot y'$ to series expansion for $m=0..2$

    $x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d}{dx}y'\right)$ to series expansion for $m=1..3$

    $x^m\cdot\left(\frac{d}{dx}y'\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d}{dx}y'\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-1+5r)\,x^{-1+r}+\left(a_1(1+r)\,(4+5r)+a_0(1+r)^2\right)x^r+\left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+r+1)\,(5k+4+5r\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+5r)=0$
- Values of r that satisfy the indicial equation

  $r\in\left\{0,\frac{1}{5}\right\}$
- Each term must be 0

  $a_1(1+r)\,(4+5r)+a_0(1+r)^2=0$
- Each term in the series must be 0, giving the recursion relation

  $((a_k+10a_{k-1}+5a_{k+1})\,k+(a_k+10a_{k-1}+5a_{k+1})\,r+a_k+8a_{k-1}+4a_{k+1})\,(k+r+1)=0$
- Shift index using $k->k+1$

$$((a_{k+1}+10a_k+5a_{k+2})(k+1)+(a_{k+1}+10a_k+5a_{k+2})r+a_{k+1}+8a_k+4a_{k+2})(k+r+2)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{10ka_k+ka_{k+1}+10ra_k+ra_{k+1}+18a_k+2a_{k+1}}{5k+5r+9}$$

- Recursion relation for $r=0$

$$a_{k+2}=-\frac{10ka_k+ka_{k+1}+18a_k+2a_{k+1}}{5k+9}$$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty}a_kx^k, a_{k+2}=-\frac{10ka_k+ka_{k+1}+18a_k+2a_{k+1}}{5k+9}, 4a_1+a_0=0\right]$$

- Recursion relation for $r=\frac{1}{5}$

$$a_{k+2}=-\frac{10ka_k+ka_{k+1}+20a_k+\frac{11}{5}a_{k+1}}{5k+10}$$

- Solution for $r=\frac{1}{5}$

$$\left[y=\sum_{k=0}^{\infty}a_kx^{k+\frac{1}{5}}, a_{k+2}=-\frac{10ka_k+ka_{k+1}+20a_k+\frac{11}{5}a_{k+1}}{5k+10}, 6a_1+\frac{36a_0}{25}=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_kx^k\right)+\left(\sum_{k=0}^{\infty}b_kx^{k+\frac{1}{5}}\right), a_{k+2}=-\frac{10ka_k+ka_{k+1}+18a_k+2a_{k+1}}{5k+9}, 4a_1+a_0=0, b_{k+2}=-\frac{10kb_k+\cdots}{}\right.$$

1.86 problem 88

Internal problem ID [8224]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 88
Date solved : `Monday, October 21, 2024 at 05:03:46 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$18x^2(1+x)\,y''+3x\left(x^2+11x+5\right)y'-\left(-5x^2-2x+1\right)y=0$$

1.86.1 Solved as second order ode using Kovacic algorithm

Time used: 0.386 (sec)

Writing the ode as

$$\left(18x^3+18x^2\right)y''+\left(3x^3+33x^2+15x\right)y'+\left(5x^2+2x-1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=18x^3+18x^2\\B&=3x^3+33x^2+15x\\C&=5x^2+2x-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{x^4 - 18x^3 - 45x^2 - 18x - 27}{144\left(x^2 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= x^4 - 18x^3 - 45x^2 - 18x - 27 \\
t &= 144\left(x^2 + x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{x^4 - 18x^3 - 45x^2 - 18x - 27}{144\left(x^2 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 156: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 4 \\
&= 0
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144(x^2+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{144} - \frac{3}{16x^2} - \frac{7}{18\,(1+x)} + \frac{1}{4x} - \frac{35}{144\,(1+x)^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12}
\end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{12} - \frac{5}{6x} - \frac{53}{12x^2} - \frac{523}{12x^3} - \frac{6659}{12x^4} - \frac{94267}{12x^5} - \frac{1432421}{12x^6} - \frac{22802941}{12x^7} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{12}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{12}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{144}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading

coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4 - 18x^3 - 45x^2 - 18x - 27}{144x^4 + 288x^3 + 144x^2} \\
&= Q + \frac{R}{144x^4 + 288x^3 + 144x^2} \\
&= \left(\frac{1}{144}\right) + \left(\frac{-20x^3 - 46x^2 - 18x - 27}{144x^4 + 288x^3 + 144x^2}\right) \\
&= \frac{1}{144} + \frac{-20x^3 - 46x^2 - 18x - 27}{144x^4 + 288x^3 + 144x^2}
\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -20. Dividing this by leading coefficient in t which is 144 gives $-\frac{5}{36}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{5}{36}\right) - (0) \\
&= -\frac{5}{36}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{12} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{36}}{\frac{1}{12}} - 0\right) &= -\frac{5}{6} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{5}{36}}{\frac{1}{12}} - 0\right) &= \frac{5}{6}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 18x^3 - 45x^2 - 18x - 27}{144\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{12}$	$\frac{5}{12}$
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{12}$	$-\frac{5}{6}$	$\frac{5}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\ &= \frac{5}{6} - \left(\frac{5}{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{7}{12\,(1+x)} + \frac{1}{4x} + (-)\left(\frac{1}{12}\right) \\ &= \frac{7}{12\,(1+x)} + \frac{1}{4x} - \frac{1}{12} \\ &= \frac{7}{12+12x} + \frac{1}{4x} - \frac{1}{12} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{12\,(1+x)} + \frac{1}{4x} - \frac{1}{12}\right)(0) + \left(\left(-\frac{7}{12\,(1+x)^2} - \frac{1}{4x^2}\right) + \left(\frac{7}{12\,(1+x)} + \frac{1}{4x} - \frac{1}{12}\right)^2 - \left(\frac{x^4 - 1}{\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{7}{12(1+x)} + \frac{1}{4x} - \frac{1}{12}\right) dx} \\
&= x^{1/4} (1+x)^{7/12} \, \mathrm{e}^{-\frac{x}{12}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{3x^3+33x^2+15x}{18x^3+18x^2} \, dx} \\
&= z_1 e^{-\frac{x}{12} - \frac{5\ln(x)}{12} - \frac{5\ln(1+x)}{12}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{12}}}{x^{5/12} (1+x)^{5/12}} \right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(1+x)^{1/6} \, \mathrm{e}^{-\frac{x}{6}}}{x^{1/6}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3+33x^2+15x}{18x^3+18x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{x}{6} - \frac{5\ln(x)}{6} - \frac{5\ln(1+x)}{6}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x}{6} - \frac{5\ln(x)}{6} - \frac{5\ln(1+x)}{6}} x^{1/3} \mathrm{e}^{\frac{x}{3}}}{(1+x)^{1/3}} dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(1+x)^{1/6}\, \mathrm{e}^{-\frac{x}{6}}}{x^{1/6}}\right) + c_2 \left(\frac{(1+x)^{1/6}\, \mathrm{e}^{-\frac{x}{6}}}{x^{1/6}} \left(\int \frac{\mathrm{e}^{-\frac{x}{6}-\frac{5\ln(x)}{6}-\frac{5\ln(1+x)}{6}} x^{1/3} \mathrm{e}^{\frac{x}{3}}}{(1+x)^{1/3}} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.86.2 Maple step by step solution

Let's solve

$18x^2(1+x)\left(\frac{d}{dx}y'\right) + 3x(x^2+11x+5)\,y' - (-5x^2-2x+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(5x^2+2x-1)y}{18x^2(1+x)} - \frac{(x^2+11x+5)y'}{6x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(x^2+11x+5)y'}{6x(1+x)} + \frac{(5x^2+2x-1)y}{18x^2(1+x)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{x^2+11x+5}{6x(1+x)}, P_3(x) = \frac{5x^2+2x-1}{18x^2(1+x)}\right]$

  - $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1} = \frac{5}{6}$

  - $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  - $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $18x^2(1+x)\left(\frac{d}{dx}y'\right) + 3x(x^2+11x+5)\,y' + (5x^2+2x-1)\,y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(18u^3-36u^2+18u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (3u^3+24u^2-42u+15)\left(\frac{d}{du}y(u)\right) + (5u^2-8u+2)\,y(u) = 0$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m=0..2$

$$u^m \cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$$

- Shift index using $k->k-m$

$$u^m \cdot y(u)=\sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..3$

$$u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m=1..3$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0r(-1+6r)\,u^{-1+r}+\left(3a_1(1+r)\,(5+6r)-2a_0(1+3r)\,(-1+6r)\right)u^r+\left(3a_2(2+r)\,(11+6r)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$3r(-1+6r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{1}{6}\right\}$$

- The coefficients of each power of u must be 0

$$[3a_1(1+r)\,(5+6r)-2a_0(1+3r)\,(-1+6r)=0, 3a_2(2+r)\,(11+6r)-2a_1(4+3r)\,(5+6r)+$$

- Solve for the dependent coefficient(s)

$$\left\{a_1=\frac{2a_0(18r^2+3r-1)}{3(6r^2+11r+5)}, a_2=\frac{2a_0(81r^3+126r^2+21r+4)}{9(6r^3+29r^2+45r+22)}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$18(-2a_k+a_{k-1}+a_{k+1})\,k^2+3(12(-2a_k+a_{k-1}+a_{k+1})\,r-2a_k+a_{k-2}-10a_{k-1}+11a_{k+1})\,k+$$

- Shift index using $k->k+2$

$18(-2a_{k+2}+a_{k+1}+a_{k+3})(k+2)^2+3(12(-2a_{k+2}+a_{k+1}+a_{k+3})r-2a_{k+2}+a_k-10a_{k+1}+11$

- Recursion relation that defines series solution to ODE

$a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+36kra_{k+1}-72kra_{k+2}+18r^2a_{k+1}-36r^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+3ra_k+42ra_{k+1}-150r}{3(6k^2+12kr+6r^2+35k+35r+51)}$

- Recursion relation for $r=0$

$a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+5a_k+16a_{k+1}-154a_{k+2}}{3(6k^2+35k+51)}$

- Solution for $r=0$

$\left[y(u)=\sum_{k=0}^{\infty}a_ku^k, a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+5a_k+16a_{k+1}-154a_{k+2}}{3(6k^2+35k+51)}, a_1=-\frac{2a_0}{15}, a\right.$

- Revert the change of variables $u=1+x$

$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^k, a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+5a_k+16a_{k+1}-154a_{k+2}}{3(6k^2+35k+51)}, a_1=-\frac{2a_0}{15}\right.$

- Recursion relation for $r=\frac{1}{6}$

$a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+48ka_{k+1}-162ka_{k+2}+\frac{11}{2}a_k+\frac{47}{2}a_{k+1}-180a_{k+2}}{3(6k^2+37k+57)}$

- Solution for $r=\frac{1}{6}$

$\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k+\frac{1}{6}}, a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+48ka_{k+1}-162ka_{k+2}+\frac{11}{2}a_k+\frac{47}{2}a_{k+1}-180a_{k+2}}{3(6k^2+37k+57)}, a_1=0, a\right.$

- Revert the change of variables $u=1+x$

$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^{k+\frac{1}{6}}, a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+48ka_{k+1}-162ka_{k+2}+\frac{11}{2}a_k+\frac{47}{2}a_{k+1}-180a_{k+2}}{3(6k^2+37k+57)}, a_1=\right.$

- Combine solutions and rename parameters

$\left[y=\left(\sum_{k=0}^{\infty}a_k(1+x)^k\right)+\left(\sum_{k=0}^{\infty}b_k(1+x)^{k+\frac{1}{6}}\right), a_{k+3}=-\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+5a}{3(6k^2+35k+51)}\right.$

1.87 problem 89

Internal problem ID [8225]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 89
Date solved : `Monday, October 21, 2024 at 05:03:47 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' + x(3+2x)\,y' - (1-x)\,y = 0$$

1.87.1 Solved as second order ode using Kovacic algorithm

Time used: 0.302 (sec)

Writing the ode as

$$2x^2y'' + \left(2x^2+3x\right)y' + (x-1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= 2x^2+3x \\ C &= x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{4x^2 + 4x + 5}{16x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 4x^2 + 4x + 5 \\
t &= 16x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{4x^2 + 4x + 5}{16x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 158: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{5}{16x^2} + \frac{1}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{4x} + \frac{1}{4x^2} - \frac{1}{8x^3} + \frac{1}{16x^5} - \frac{3}{64x^6} - \frac{1}{128x^7} + \frac{11}{256x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{4x^2 + 4x + 5}{16x^2} \\
&= Q + \frac{R}{16x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{4x + 5}{16x^2}\right) \\
&= \frac{1}{4} + \frac{4x + 5}{16x^2}
\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 16 gives $\frac{1}{4}$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{1}{4}\right) - (0) \\
&= \frac{1}{4}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &= \frac{1}{4} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &= -\frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 + 4x + 5}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	$\frac{1}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{1}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{4} - \left(-\frac{1}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{4x} + (-)\left(\frac{1}{2}\right) \\
&= -\frac{1}{4x} - \frac{1}{2} \\
&= -\frac{1}{4x} - \frac{1}{2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{4x} - \frac{1}{2}\right)(0) + \left(\left(\frac{1}{4x^2}\right) + \left(-\frac{1}{4x} - \frac{1}{2}\right)^2 - \left(\frac{4x^2+4x+5}{16x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{4x} - \frac{1}{2}\right) dx} \\
&= \frac{\mathrm{e}^{-\frac{x}{2}}}{x^{1/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^2+3x}{2x^2} \, dx} \\
&= z_1 e^{-\frac{x}{2} - \frac{3\ln(x)}{4}} \\
&= z_1\left(\frac{\mathrm{e}^{-\frac{x}{2}}}{x^{3/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^{-x}}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2+3x}{2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x-\frac{3\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\sqrt{x}\,e^{x} - \frac{\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{e^{-x}}{x}\right) + c_2\left(\frac{e^{-x}}{x}\left(\sqrt{x}\,e^{x} - \frac{\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right)}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.87.2 Maple step by step solution

Let's solve

$2x^2\left(\frac{d}{dx}y'\right) + x(3+2x)\,y' - (1-x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(x-1)y}{2x^2} - \frac{(3+2x)y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(3+2x)y'}{2x} + \frac{(x-1)y}{2x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{3+2x}{2x}, P_3(x) = \frac{x-1}{2x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{3}{2}$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -\frac{1}{2}$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $2x^2\left(\frac{d}{dx}y'\right) + x(3 + 2x)\, y' + (x - 1)\, y = 0$
- Assume series solution for y
  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$
    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k - m$
    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 1..2$
    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$
  - Shift index using $k- >k + 1 - m$
    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$
  - Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion
    $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r}$
    Rewrite ODE with series expansions
    $a_0(1 + r)\,(-1 + 2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k + r + 1)\,(2k + 2r - 1) + a_{k-1}(2k + 2r - 1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+r)(-1+2r)=0$
- Values of r that satisfy the indicial equation
  $r\in\left\{-1,\frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $2(a_k(k+r+1)+a_{k-1})\left(k+r-\frac{1}{2}\right)=0$
- Shift index using $k->k+1$
  $2(a_{k+1}(k+2+r)+a_k)\left(k+\frac{1}{2}+r\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=-\frac{a_k}{k+2+r}$
- Recursion relation for $r=-1$
  $a_{k+1}=-\frac{a_k}{k+1}$
- Solution for $r=-1$
  $\left[y=\sum_{k=0}^{\infty}a_k x^{k-1}, a_{k+1}=-\frac{a_k}{k+1}\right]$
- Recursion relation for $r=\frac{1}{2}$
  $a_{k+1}=-\frac{a_k}{k+\frac{5}{2}}$
- Solution for $r=\frac{1}{2}$
  $\left[y=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}, a_{k+1}=-\frac{a_k}{k+\frac{5}{2}}\right]$
- Combine solutions and rename parameters
  $\left[y=\left(\sum_{k=0}^{\infty}a_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{1}{2}}\right), a_{k+1}=-\frac{a_k}{k+1}, b_{k+1}=-\frac{b_k}{k+\frac{5}{2}}\right]$

1.88 problem 90

Internal problem ID [8226]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 90
Date solved : `Monday, October 21, 2024 at 05:03:49 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' + x(5+x)\,y' - (2-3x)\,y = 0$$

1.88.1 Solved as second order ode using Kovacic algorithm

Time used: 0.335 (sec)

Writing the ode as

$$2x^2y'' + \left(x^2+5x\right)y' + (3x-2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= x^2+5x \\ C &= 3x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 14x + 21}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 14x + 21$$
$$t = 16x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 14x + 21}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 160: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 2 \\
&= 0
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{16} - \frac{7}{8x} + \frac{21}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{4} - \frac{7}{4x} - \frac{7}{2x^2} - \frac{49}{2x^3} - \frac{196}{x^4} - \frac{1715}{x^5} - \frac{31899}{2x^6} - \frac{309729}{2x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{16}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 14x + 21}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{1}{16}\right) + \left(\frac{-14x + 21}{16x^2}\right) \\ &= \frac{1}{16} + \frac{-14x + 21}{16x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -14. Dividing this by leading coefficient in t which is 16 gives $-\frac{7}{8}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{7}{8}\right) - (0)\\ &= -\frac{7}{8}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{4}\\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{7}{8}}{\frac{1}{4}} - 0\right) &= -\frac{7}{4}\\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{7}{8}}{\frac{1}{4}} - 0\right) &= \frac{7}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 14x + 21}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{4}$	$-\frac{7}{4}$	$\frac{7}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{7}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right)\\ &= \frac{7}{4} - \left(\frac{7}{4}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{7}{4x} + (-)\left(\frac{1}{4}\right) \\
&= \frac{7}{4x} - \frac{1}{4} \\
&= -\frac{x-7}{4x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{4x} - \frac{1}{4}\right)(0) + \left(\left(-\frac{7}{4x^2}\right) + \left(\frac{7}{4x} - \frac{1}{4}\right)^2 - \left(\frac{x^2 - 14x + 21}{16x^2}\right) \right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{7}{4x} - \frac{1}{4}\right) dx} \\
&= x^{7/4} \mathrm{e}^{-\frac{x}{4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x^2+5x}{2x^2} \, dx} \\
&= z_1 e^{-\frac{x}{4} - \frac{5\ln(x)}{4}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{4}}}{x^{5/4}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\,e^{-\frac{x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+5x}{2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x}{2}-\frac{5\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{2\,e^{\frac{x}{2}}}{5x^{5/2}} - \frac{2\,e^{\frac{x}{2}}}{15x^{3/2}} - \frac{2\,e^{\frac{x}{2}}}{15\sqrt{x}} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,\sqrt{x}}{2}\right)}{15}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\,e^{-\frac{x}{2}}\right) + c_2\left(\sqrt{x}\,e^{-\frac{x}{2}}\left(-\frac{2\,e^{\frac{x}{2}}}{5x^{5/2}} - \frac{2\,e^{\frac{x}{2}}}{15x^{3/2}} - \frac{2\,e^{\frac{x}{2}}}{15\sqrt{x}} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,\sqrt{x}}{2}\right)}{15}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.88.2 Maple step by step solution

Let's solve

$2x^2\left(\frac{d}{dx}y'\right) + x(5+x)\,y' - (2-3x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(3x-2)y}{2x^2} - \frac{(5+x)y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(5+x)y'}{2x} + \frac{(3x-2)y}{2x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{5+x}{2x}, P_3(x) = \frac{3x-2}{2x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{5}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -1$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2\left(\frac{d}{dx}y'\right) + x(5+x)\,y' + (3x-2)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(2+r)(-1+2r)x^r + \left(\sum_{k=1}^{\infty} (a_k(k+r+2)(2k+2r-1) + a_{k-1}(k+r+2))x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(2+r)(-1+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-2, \frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $2(k+r+2)\left(\left(k+r-\frac{1}{2}\right)a_k + \frac{a_{k-1}}{2}\right) = 0$
- Shift index using $k->k+1$
  $2(k+r+3)\left(\left(k+\frac{1}{2}+r\right)a_{k+1} + \frac{a_k}{2}\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{a_k}{2k+1+2r}$
- Recursion relation for $r = -2$
  $a_{k+1} = -\frac{a_k}{2k-3}$
- Solution for $r = -2$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+1} = -\frac{a_k}{2k-3}\right]$
- Recursion relation for $r = \frac{1}{2}$
  $a_{k+1} = -\frac{a_k}{2k+2}$
- Solution for $r = \frac{1}{2}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k}{2k+2}\right]$
- Combine solutions and rename parameters
  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = -\frac{a_k}{2k-3}, b_{k+1} = -\frac{b_k}{2k+2}\right]$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 91
Date solved : `Monday, October 21, 2024 at 05:03:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2y'' + x(1+x)\,y' - y = 0$$

1.89.1 Solved as second order ode using Kovacic algorithm

Time used: 0.510 (sec)

Writing the ode as

$$3x^2y'' + \left(x^2+x\right)y' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2 \\ B &= x^2+x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{x^2 + 2x + 7}{36x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= x^2 + 2x + 7 \\
t &= 36x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{x^2 + 2x + 7}{36x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 162: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 2 \\
&= 0
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$
L = [1, 2]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{1}{36} + \frac{7}{36x^2} + \frac{1}{18x}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{6}
\end{aligned}
$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$
v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0
$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i \qquad (8)
\end{aligned}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{6} + \frac{1}{6x} + \frac{1}{2x^2} - \frac{1}{2x^3} - \frac{1}{4x^4} + \frac{7}{4x^5} - \frac{7}{4x^6} - \frac{17}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 2x + 7}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{36}\right) + \left(\frac{2x + 7}{36x^2}\right) \\ &= \frac{1}{36} + \frac{2x + 7}{36x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 2. Dividing this by leading coefficient in t which is 36 gives $\frac{1}{18}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{18}\right) - (0) \\ &= \frac{1}{18} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{6} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{18}}{\frac{1}{6}} - 0\right) &= \frac{1}{6} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{18}}{\frac{1}{6}} - 0\right) &= -\frac{1}{6} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 2x + 7}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$\frac{1}{6}$	$-\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= -\frac{1}{6} - \left(-\frac{1}{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{6x} + (-)\left(\frac{1}{6}\right) \\ &= -\frac{1}{6x} - \frac{1}{6} \\ &= -\frac{1+x}{6x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(-\frac{1}{6x} - \frac{1}{6}\right)(0) + \left(\left(\frac{1}{6x^2}\right) + \left(-\frac{1}{6x} - \frac{1}{6}\right)^2 - \left(\frac{x^2+2x+7}{36x^2}\right)\right) &= 0 \\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{6x} - \frac{1}{6}\right) dx} \\ &= \frac{e^{-\frac{x}{6}}}{x^{1/6}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2+x}{3x^2} \, dx} \\ &= z_1 e^{-\frac{x}{6} - \frac{\ln(x)}{6}} \\ &= z_1 \left(\frac{e^{-\frac{x}{6}}}{x^{1/6}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^{-\frac{x}{3}}}{x^{1/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+x}{3x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int e^{-\frac{x}{3}-\frac{\ln(x)}{3}} x^{2/3} e^{\frac{2x}{3}}\, dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{e^{-\frac{x}{3}}}{x^{1/3}}\right) + c_2 \left(\frac{e^{-\frac{x}{3}}}{x^{1/3}} \left(\int e^{-\frac{x}{3}-\frac{\ln(x)}{3}} x^{2/3} e^{\frac{2x}{3}}\, dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.89.2 Maple step by step solution

Let's solve

$3x^2 \left(\frac{d}{dx} y'\right) + x(1+x)\, y' - y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$

- Isolate 2nd derivative

  $\frac{d}{dx} y' = \frac{y}{3x^2} - \frac{(1+x)y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx} y' + \frac{(1+x)y'}{3x} - \frac{y}{3x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{1+x}{3x}, P_3(x) = -\frac{1}{3x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = \frac{1}{3}$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{1}{3}$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $3x^2\left(\frac{d}{dx}y'\right) + x(1+x)\,y' - y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- ○ Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ○ Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+3r)\,(-1+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(3k+3r+1)\,(k+r-1) + a_{k-1}(k+r-1)\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+3r)\,(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{1, -\frac{1}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

$$3(k+r-1)\left(\left(k+r+\frac{1}{3}\right)a_k+\frac{a_{k-1}}{3}\right)=0$$

- Shift index using $k->k+1$

$$3(k+r)\left(\left(k+\frac{4}{3}+r\right)a_{k+1}+\frac{a_k}{3}\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=-\frac{a_k}{3k+4+3r}$$

- Recursion relation for $r=1$

$$a_{k+1}=-\frac{a_k}{3k+7}$$

- Solution for $r=1$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k+1},a_{k+1}=-\frac{a_k}{3k+7}\right]$$

- Recursion relation for $r=-\frac{1}{3}$

$$a_{k+1}=-\frac{a_k}{3k+3}$$

- Solution for $r=-\frac{1}{3}$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k-\frac{1}{3}},a_{k+1}=-\frac{a_k}{3k+3}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k x^{k+1}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k-\frac{1}{3}}\right),a_{k+1}=-\frac{a_k}{3k+7},b_{k+1}=-\frac{b_k}{3k+3}\right]$$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' - xy' + (1-2x)\,y = 0$$

1.90.1 Solved as second order ode using Kovacic algorithm

Time used: 0.209 (sec)

Writing the ode as

$$2x^2y'' - xy' + (1-2x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= -x \\ C &= 1-2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3 + 16x}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 + 16x \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3 + 16x}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 164: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{x} - \frac{3}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = 1,\ e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$
\begin{aligned}
d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\
&= \frac{1}{2}(1-(1)) \\
&= 0
\end{aligned}
$$

We now form the following rational function

$$
\begin{aligned}
\theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\
&= \frac{1}{2}\left(\frac{1}{(x-(0))}\right) \\
&= \frac{1}{2x}
\end{aligned}
$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$
p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}
$$

Since $d=0$, then letting

$$
p = 1 \tag{2A}
$$

Substituting p and θ into Eq. (1A) gives

$$
0 = 0
$$

And solving for p gives

$$
p = 1
$$

Now that $p(x)$ is found let

$$
\begin{aligned}
\phi &= \theta + \frac{p'}{p} \\
&= \frac{1}{2x}
\end{aligned}
$$

Let ω be the solution of

$$
\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0
$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{1-16x}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1+4\sqrt{x}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1+4\sqrt{x}}{4x} dx} \\ &= x^{1/4} \mathrm{e}^{2\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x}{2x^2} \, dx} \\ &= z_1 e^{\frac{\ln(x)}{4}} \\ &= z_1 \left(x^{1/4}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\, \mathrm{e}^{2\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{2x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\frac{\ln(x)}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{\mathrm{e}^{-4\sqrt{x}}}{2}\right) \end{aligned}$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\sqrt{x}\, e^{2\sqrt{x}}\right) + c_2 \left(\sqrt{x}\, e^{2\sqrt{x}} \left(-\frac{e^{-4\sqrt{x}}}{2}\right)\right)$$

Will add steps showing solving for IC soon.

1.90.2 Maple step by step solution

Let's solve

$2x^2 \left(\frac{d}{dx} y'\right) - x y' + (1 - 2x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$

- Isolate 2nd derivative

Solve

$$3x^2y'' + x(1 + x)\, y' - (1 + 3x)\, y = 0$$

1.91.1 Solved as second order ode using Kovacic algorithm

Time used: 0.648 (sec)

Writing the ode as

$$3x^2y'' + \left(x^2 + x\right) y' + (-3x - 1)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2 \\ B &= x^2 + x \\ C &= -3x - 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 38x + 7}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 + 38x + 7$$
$$t = 36x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 + 38x + 7}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 166: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{19}{18x} + \frac{7}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{6} + \frac{19}{6x} - \frac{59}{2x^2} + \frac{1121}{2x^3} - \frac{53041}{4x^4} + \frac{1404613}{4x^5} - \frac{39845827}{4x^6} + \frac{1184064097}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 38x + 7}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{36}\right) + \left(\frac{38x + 7}{36x^2}\right) \\ &= \frac{1}{36} + \frac{38x + 7}{36x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 38. Dividing this by leading coefficient in t which is 36 gives $\frac{19}{18}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{19}{18}\right) - (0) \\ &= \frac{19}{18} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{6} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{19}{18}}{\frac{1}{6}} - 0\right) &&= \frac{19}{6} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{19}{18}}{\frac{1}{6}} - 0\right) &&= -\frac{19}{6} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 38x + 7}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$\frac{19}{6}$	$-\frac{19}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{19}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+\right) \\ &= \frac{19}{6} - \left(\frac{7}{6}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{7}{6x} + \left(\frac{1}{6}\right) \\
&= \frac{7}{6x} + \frac{1}{6} \\
&= \frac{7+x}{6x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{7}{6x} + \frac{1}{6}\right)(2x + a_1) + \left(\left(-\frac{7}{6x^2}\right) + \left(\frac{7}{6x} + \frac{1}{6}\right)^2 - \left(\frac{x^2 + 38x + 7}{36x^2}\right) \right) = 0$$

$$\frac{(-a_1 + 20)\, x - 2a_0 + 7a_1}{3x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 70, a_1 = 20\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 20x + 70$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x^2 + 20x + 70)\, e^{\int \left(\frac{7}{6x} + \frac{1}{6}\right) dx} \\
&= (x^2 + 20x + 70)\, e^{\frac{x}{6} + \frac{7 \ln(x)}{6}} \\
&= (x^2 + 20x + 70)\, x^{7/6} e^{\frac{x}{6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+x}{3x^2}\,dx} \\
&= z_1 e^{-\frac{x}{6}-\frac{\ln(x)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{6}}}{x^{1/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (x^2 + 20x + 70)\, x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+x}{3x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{(x^2+20x+70)^2\, x^2} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((x^2+20x+70)\, x\right) + c_2\left((x^2+20x+70)\, x \left(\int \frac{\mathrm{e}^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{(x^2+20x+70)^2\, x^2} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.91.2 Maple step by step solution

Let's solve

$3x^2\left(\frac{d}{dx}y'\right)+x(1+x)\,y'-(1+3x)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=\frac{(1+3x)y}{3x^2}-\frac{(1+x)y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{(1+x)y'}{3x}-\frac{(1+3x)y}{3x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{1+x}{3x}, P_3(x)=-\frac{1+3x}{3x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=\frac{1}{3}$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\bigg|_{x=0}=-\frac{1}{3}$

  - $x=0$is a regular singular point

    Check to see if $x_0=0$ is a regular singular point

    $x_0=0$

- Multiply by denominators

$3x^2\left(\frac{d}{dx}y'\right)+x(1+x)\,y'+(-3x-1)\,y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m\cdot y$ to series expansion for $m=0..1$

    $x^m\cdot y=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot y'$ to series expansion for $m=1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

$$x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 (1+3r)\,(-1+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k (3k+3r+1)\,(k+r-1) + a_{k-1}(k-4+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+3r)\,(-1+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{1, -\frac{1}{3}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $3\left(k+r+\frac{1}{3}\right)(k+r-1)\, a_k + a_{k-1}(k-4+r) = 0$
- Shift index using $k- >k+1$
  $3\left(k+\frac{4}{3}+r\right)(k+r)\, a_{k+1} + a_k(k+r-3) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{a_k (k+r-3)}{(3k+4+3r)(k+r)}$
- Recursion relation for $r = 1$; series terminates at $k = 2$
  $a_{k+1} = -\frac{a_k (k-2)}{(3k+7)(k+1)}$
- Apply recursion relation for $k = 0$
  $a_1 = \frac{2a_0}{7}$
- Apply recursion relation for $k = 1$
  $a_2 = \frac{a_1}{20}$
- Express in terms of a_0
  $a_2 = \frac{a_0}{70}$
- Terminating series solution of the ODE for $r = 1$. Use reduction of order to find the second li
  $y = a_0 \cdot \left(1 + \frac{2}{7}x + \frac{1}{70}x^2\right)$
- Recursion relation for $r = -\frac{1}{3}$
  $a_{k+1} = -\frac{a_k \left(k-\frac{10}{3}\right)}{(3k+3)\left(k-\frac{1}{3}\right)}$

- Solution for $r=-\frac{1}{3}$

  $$\left[y=\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+1}=-\frac{a_k\left(k-\frac{10}{3}\right)}{(3k+3)\left(k-\frac{1}{3}\right)}\right]$$

- Combine solutions and rename parameters

  $$\left[y=a_0\cdot\left(1+\frac{2}{7}x+\frac{1}{70}x^2\right)+\left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{3}}\right), b_{k+1}=-\frac{b_k\left(k-\frac{10}{3}\right)}{(3k+3)\left(k-\frac{1}{3}\right)}\right]$$

1.92 problem 94

Internal problem ID [8230]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 94
Date solved : `Monday, October 21, 2024 at 05:03:54 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(3+x)\,y''+x(1+5x)\,y'+(1+x)\,y=0$$

1.92.1 Solved as second order ode using Kovacic algorithm

Time used: 0.345 (sec)

Writing the ode as

$$\left(2x^3+6x^2\right)y''+\left(5x^2+x\right)y'+(1+x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x^3+6x^2\\B&=5x^2+x\\C&=1+x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3x^2 - 30x - 35}{16\left(x^2 + 3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -3x^2 - 30x - 35$$
$$t = 16\left(x^2 + 3x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3x^2 - 30x - 35}{16\left(x^2 + 3x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 168: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2+3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -3$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{5}{108\,(3+x)} + \frac{7}{36\,(3+x)^2} - \frac{35}{144x^2} - \frac{5}{108x}
$$

For the pole at $x = -3$ let b be the coefficient of $\frac{1}{(3+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}
\end{aligned}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-3x^2 - 30x - 35}{16\,(x^2+3x)^2}
$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{4}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-3x^2-30x-35}{16\left(x^2+3x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-3	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right)\\
&= \frac{1}{4}-\left(\frac{1}{4}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{6\left(3+x\right)} + \frac{5}{12x} + (-)\left(0\right) \\
&= -\frac{1}{6\left(3+x\right)} + \frac{5}{12x} \\
&= \frac{x+5}{4x\left(3+x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{6\left(3+x\right)} + \frac{5}{12x}\right)(0) + \left(\left(\frac{1}{6\left(3+x\right)^2} - \frac{5}{12x^2}\right) + \left(-\frac{1}{6\left(3+x\right)} + \frac{5}{12x}\right)^2 - \left(\frac{-3x^2 - 30x - 3}{16\left(x^2+3x\right)^2}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{6(3+x)} + \frac{5}{12x}\right) dx} \\
&= \frac{x^{5/12}}{\left(3+x\right)^{1/6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{5x^2+x}{2x^3+6x^2} \, dx} \\
&= z_1 e^{-\frac{\ln(x)}{12} - \frac{7\ln(3+x)}{6}} \\
&= z_1\left(\frac{1}{x^{1/12}\left(3+x\right)^{7/6}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{(3+x)^{4/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5x^2+x}{2x^3+6x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{6}-\frac{7\ln(3+x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{6}-\frac{7\ln(3+x)}{3}} (3+x)^{8/3}}{x^{2/3}} dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/3}}{(3+x)^{4/3}} \right) + c_2 \left(\frac{x^{1/3}}{(3+x)^{4/3}} \left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{6}-\frac{7\ln(3+x)}{3}} (3+x)^{8/3}}{x^{2/3}} dx \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.92.2 Maple step by step solution

Let's solve

$2x^2(3+x)\left(\frac{d}{dx}y'\right) + x(1+5x)\,y' + (1+x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(1+x)y}{2x^2(3+x)} - \frac{(1+5x)y'}{2x(3+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y' + \frac{(1+5x)y'}{2x(3+x)} + \frac{(1+x)y}{2x^2(3+x)} = 0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{1+5x}{2x(3+x)}, P_3(x) = \frac{1+x}{2x^2(3+x)}\right]$
- ○ $(3+x) \cdot P_2(x)$ is analytic at $x = -3$

  $\left.((3+x) \cdot P_2(x))\right|_{x=-3} = \frac{7}{3}$
- ○ $(3+x)^2 \cdot P_3(x)$ is analytic at $x = -3$

  $\left.((3+x)^2 \cdot P_3(x))\right|_{x=-3} = 0$
- ○ $x = -3$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -3$

- Multiply by denominators

  $2x^2(3+x)\left(\frac{d}{dx}y'\right) + x(1+5x)\,y' + (1+x)\,y = 0$
- Change variables using $x = u - 3$ so that the regular singular point is at $u = 0$

  $(2u^3 - 12u^2 + 18u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (5u^2 - 29u + 42)\left(\frac{d}{du}y(u)\right) + (-2+u)\,y(u) = 0$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$
- ○ Shift index using $k- > k - m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
- ○ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
- ○ Shift index using $k- > k + 1 - m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$
- ○ Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

$$u^{m} \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^{m} \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$6a_0 r(4+3r)\, u^{-1+r} + \left(6a_1(1+r)(7+3r) - a_0(12r^2+17r+2)\right) u^{r} + \left(\sum_{k=1}^{\infty} (6a_{k+1}(k+r+1)(3k$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$6r(4+3r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{4}{3}\right\}$$

- Each term must be 0

$$6a_1(1+r)(7+3r) - a_0(12r^2+17r+2) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$2(-6a_k + a_{k-1} + 9a_{k+1})\, k^2 + (4(-6a_k + a_{k-1} + 9a_{k+1})\, r - 17a_k - a_{k-1} + 60a_{k+1})\, k + 2(-6a_k +$$

- Shift index using $k->k+1$

$$2(-6a_{k+1} + a_k + 9a_{k+2})\,(k+1)^2 + (4(-6a_{k+1} + a_k + 9a_{k+2})\, r - 17a_{k+1} - a_k + 60a_{k+2})\,(k+1)$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{2k^2a_k - 12k^2a_{k+1} + 4kra_k - 24kra_{k+1} + 2r^2a_k - 12r^2a_{k+1} + 3ka_k - 41ka_{k+1} + 3ra_k - 41ra_{k+1} + a_k - 31a_{k+1}}{6(3k^2+6kr+3r^2+16k+16r+20)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{2k^2a_k - 12k^2a_{k+1} + 3ka_k - 41ka_{k+1} + a_k - 31a_{k+1}}{6(3k^2+16k+20)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2a_k - 12k^2a_{k+1} + 3ka_k - 41ka_{k+1} + a_k - 31a_{k+1}}{6(3k^2+16k+20)}, 42a_1 - 2a_0 = 0\right]$$

- Revert the change of variables $u = 3 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (3+x)^k, a_{k+2} = -\frac{2k^2a_k - 12k^2a_{k+1} + 3ka_k - 41ka_{k+1} + a_k - 31a_{k+1}}{6(3k^2+16k+20)}, 42a_1 - 2a_0 = 0\right]$$

- Recursion relation for $r = -\frac{4}{3}$

$$a_{k+2} = -\frac{2k^2a_k - 12k^2a_{k+1} - \frac{7}{3}ka_k - 9ka_{k+1} + \frac{5}{9}a_k + \frac{7}{3}a_{k+1}}{6(3k^2+8k+4)}$$

- Solution for $r = -\frac{4}{3}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{4}{3}}, a_{k+2} = -\frac{2k^2a_k - 12k^2a_{k+1} - \frac{7}{3}ka_k - 9ka_{k+1} + \frac{5}{9}a_k + \frac{7}{3}a_{k+1}}{6(3k^2+8k+4)}, -6a_1 - \frac{2a_0}{3} = 0\right]$$

- Revert the change of variables $u = 3 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (3+x)^{k-\frac{4}{3}}, a_{k+2} = -\frac{2k^2 a_k - 12k^2 a_{k+1} - \frac{7}{3} k a_k - 9k a_{k+1} + \frac{5}{9} a_k + \frac{7}{3} a_{k+1}}{6(3k^2+8k+4)}, -6a_1 - \frac{2a_0}{3} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (3+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (3+x)^{k-\frac{4}{3}}\right), a_{k+2} = -\frac{2k^2 a_k - 12k^2 a_{k+1} + 3k a_k - 41k a_{k+1} + a_k - 31 a_{k+1}}{6(3k^2+16k+20)}, 42a$$

1.93 problem 95

Internal problem ID [8231]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 95
Date solved : `Monday, October 21, 2024 at 05:03:55 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(4+x)\,y''-x(1-3x)\,y'+y=0$$

1.93.1 Solved as second order ode using Kovacic algorithm

Time used: 0.585 (sec)

Writing the ode as

$$x^2(4+x)\,y''+\left(3x^2-x\right)y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(4+x) \\ B &= 3x^2-x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^2 - 6x - 7}{4\left(x^2 + 4x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2 - 6x - 7 \\ t &= 4\left(x^2 + 4x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^2 - 6x - 7}{4\left(x^2 + 4x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 170: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + 4x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -4$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{128\,(4+x)} - \frac{7}{64x^2} + \frac{65}{64\,(4+x)^2} - \frac{5}{128x}$$

For the pole at $x = -4$ let b be the coefficient of $\frac{1}{(4+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{65}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{8} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 - 6x - 7}{4\,(x^2 + 4x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{3x^2-6x-7}{4\left(x^2+4x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-4	2	0	$\frac{13}{8}$	$-\frac{5}{8}$
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=-\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right)\\
&= -\frac{1}{2}-\left(-\frac{1}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{5}{8\,(4+x)} + \frac{1}{8x} + (-)\,(0) \\
&= -\frac{5}{8\,(4+x)} + \frac{1}{8x} \\
&= -\frac{x-1}{2x\,(4+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{5}{8\,(4+x)} + \frac{1}{8x}\right)(0) + \left(\left(\frac{5}{8\,(4+x)^2} - \frac{1}{8x^2}\right) + \left(-\frac{5}{8\,(4+x)} + \frac{1}{8x}\right)^2 - \left(\frac{3x^2-6x-7}{4\,(x^2+4x)^2}\right)\right) = 0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{5}{8(4+x)} + \frac{1}{8x}\right) dx} \\
&= \frac{x^{1/8}}{(4+x)^{5/8}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^2-x}{x^2(4+x)}\, dx} \\
&= z_1 e^{\frac{\ln(x)}{8} - \frac{13\ln(4+x)}{8}} \\
&= z_1 \left(\frac{x^{1/8}}{(4+x)^{13/8}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{x^{1/4}}{(4+x)^{9/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^2-x}{x^2(4+x)}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{\ln(x)}{4}-\frac{13\ln(4+x)}{4}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{\ln(x)}{4}-\frac{13\ln(4+x)}{4}}(4+x)^{9/2}}{\sqrt{x}}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/4}}{(4+x)^{9/4}}\right) + c_2\left(\frac{x^{1/4}}{(4+x)^{9/4}}\left(\int \frac{\mathrm{e}^{\frac{\ln(x)}{4}-\frac{13\ln(4+x)}{4}}(4+x)^{9/2}}{\sqrt{x}}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.93.2 Maple step by step solution

Let's solve

$x^2(4+x)\left(\frac{d}{dx}y'\right) - x(1-3x)\,y' + y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{x^2(4+x)} - \frac{(3x-1)y'}{x(4+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y' + \frac{(3x-1)y'}{x(4+x)} + \frac{y}{x^2(4+x)} = 0$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x) = \frac{3x-1}{x(4+x)}, P_3(x) = \frac{1}{x^2(4+x)}\right]$

- $(4+x) \cdot P_2(x)$ is analytic at $x = -4$

  $\left((4+x) \cdot P_2(x)\right)\bigg|_{x=-4} = \frac{13}{4}$

- $(4+x)^2 \cdot P_3(x)$ is analytic at $x = -4$

  $\left((4+x)^2 \cdot P_3(x)\right)\bigg|_{x=-4} = 0$

- $x = -4$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -4$

- Multiply by denominators

  $x^2(4+x)\left(\frac{d}{dx}y'\right) + x(3x-1)y' + y = 0$

- Change variables using $x = u - 4$ so that the regular singular point is at $u = 0$

  $(u^3 - 8u^2 + 16u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (3u^2 - 25u + 52)\left(\frac{d}{du}y(u)\right) + y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

$$4a_0r(9+4r)\,u^{-1+r}+\left(4a_1(1+r)\,(13+4r)-a_0(8r^2+17r-1)\right)u^r+\left(\sum_{k=1}^{\infty}\left(4a_{k+1}(k+1+r)\,(4k\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $4r(9+4r)=0$
- Values of r that satisfy the indicial equation
  $r\in\left\{0,-\frac{9}{4}\right\}$
- Each term must be 0
  $4a_1(1+r)\,(13+4r)-a_0(8r^2+17r-1)=0$
- Each term in the series must be 0, giving the recursion relation
  $(-8a_k+a_{k-1}+16a_{k+1})\,k^2+(2(-8a_k+a_{k-1}+16a_{k+1})\,r-17a_k+68a_{k+1})\,k+(-8a_k+a_{k-1}+$
- Shift index using $k->k+1$
  $(-8a_{k+1}+a_k+16a_{k+2})\,(k+1)^2+(2(-8a_{k+1}+a_k+16a_{k+2})\,r-17a_{k+1}+68a_{k+2})\,(k+1)+(-$
- Recursion relation that defines series solution to ODE
  $a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}+2kra_k-16kra_{k+1}+r^2a_k-8r^2a_{k+1}+2ka_k-33ka_{k+1}+2ra_k-33ra_{k+1}-24a_{k+1}}{4(4k^2+8kr+4r^2+25k+25r+34)}$
- Recursion relation for $r=0$
  $a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}+2ka_k-33ka_{k+1}-24a_{k+1}}{4(4k^2+25k+34)}$
- Solution for $r=0$
  $\left[y(u)=\sum_{k=0}^{\infty}a_ku^k, a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}+2ka_k-33ka_{k+1}-24a_{k+1}}{4(4k^2+25k+34)}, 52a_1+a_0=0\right]$
- Revert the change of variables $u=4+x$
  $\left[y=\sum_{k=0}^{\infty}a_k(4+x)^k, a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}+2ka_k-33ka_{k+1}-24a_{k+1}}{4(4k^2+25k+34)}, 52a_1+a_0=0\right]$
- Recursion relation for $r=-\frac{9}{4}$
  $a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}-\frac{5}{2}ka_k+3ka_{k+1}+\frac{9}{16}a_k+\frac{39}{4}a_{k+1}}{4(4k^2+7k-2)}$
- Solution for $r=-\frac{9}{4}$
  $\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k-\frac{9}{4}}, a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}-\frac{5}{2}ka_k+3ka_{k+1}+\frac{9}{16}a_k+\frac{39}{4}a_{k+1}}{4(4k^2+7k-2)}, -20a_1-\frac{5a_0}{4}=0\right]$
- Revert the change of variables $u=4+x$
  $\left[y=\sum_{k=0}^{\infty}a_k(4+x)^{k-\frac{9}{4}}, a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}-\frac{5}{2}ka_k+3ka_{k+1}+\frac{9}{16}a_k+\frac{39}{4}a_{k+1}}{4(4k^2+7k-2)}, -20a_1-\frac{5a_0}{4}=0\right]$
- Combine solutions and rename parameters
  $\left[y=\left(\sum_{k=0}^{\infty}a_k(4+x)^k\right)+\left(\sum_{k=0}^{\infty}b_k(4+x)^{k-\frac{9}{4}}\right), a_{k+2}=-\frac{k^2a_k-8k^2a_{k+1}+2ka_k-33ka_{k+1}-24a_{k+1}}{4(4k^2+25k+34)}, 52a_1+\right.$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' + 5xy' + (1+x)\,y = 0$$

1.94.1 Solved as second order ode using Kovacic algorithm

Time used: 0.279 (sec)

Writing the ode as

$$2x^2y'' + 5xy' + (1+x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= 5x \\ C &= 1+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-3 - 8x}{16x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -3 - 8x \\
t &= 16x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-3 - 8x}{16x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 172: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} - \frac{1}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$
\begin{aligned}
d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\
&= \frac{1}{2}(1-(1)) \\
&= 0
\end{aligned}
$$

We now form the following rational function

$$
\begin{aligned}
\theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\
&= \frac{1}{2}\left(\frac{1}{(x-(0))}\right) \\
&= \frac{1}{2x}
\end{aligned}
$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$
p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}
$$

Since $d=0$, then letting

$$
p = 1 \tag{2A}
$$

Substituting p and θ into Eq. (1A) gives

$$
0 = 0
$$

And solving for p gives

$$
p = 1
$$

Now that $p(x)$ is found let

$$
\begin{aligned}
\phi &= \theta + \frac{p'}{p} \\
&= \frac{1}{2x}
\end{aligned}
$$

Let ω be the solution of

$$
\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0
$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{1+8x}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + 2\sqrt{2}\,\sqrt{-x}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1+2\sqrt{2}\,\sqrt{-x}}{4x} dx} \\ &= x^{1/4} \mathrm{e}^{\sqrt{2}\,\sqrt{-x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{5x}{2x^2}\, dx} \\ &= z_1 e^{-\frac{5\ln(x)}{4}} \\ &= z_1 \left(\frac{1}{x^{5/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{\sqrt{2}\,\sqrt{-x}}}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{5x}{2x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{5\ln(x)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{\sqrt{2}\,\sqrt{-x}\left(1 - \mathrm{e}^{-2\sqrt{2}\,\sqrt{-x}}\right)}{2\sqrt{x}} \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{\sqrt{2}\,\sqrt{-x}}}{x}\right) + c_2 \left(\frac{e^{\sqrt{2}\,\sqrt{-x}}}{x}\left(-\frac{\sqrt{2}\,\sqrt{-x}\left(1-e^{-2\sqrt{2}\,\sqrt{-x}}\right)}{2\sqrt{x}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.94.2 Maple step by step solution

Let's solve

$2x^2\left(\frac{d}{dx}y'\right) + 5xy' + (1+x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(1+x)y}{2x^2} - \frac{5y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{5y'}{2x} + \frac{(1+x)y}{2x^2} = 0$

- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{5}{2x}, P_3(x) = \frac{1+x}{2x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{5}{2}$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{1}{2}$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2\left(\frac{d}{dx}y'\right) + 5xy' + (1+x)\,y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$
  - Convert $x^2 \cdot \left(\frac{d}{dx} y'\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(1+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(2k+2r+1) + a_{k-1}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{-1, -\frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $2(k+r+1)\left(k+r+\frac{1}{2}\right) a_k + a_{k-1} = 0$
- Shift index using $k- >k + 1$

  $2(k+2+r)\left(k+\frac{3}{2}+r\right) a_{k+1} + a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{(k+2+r)(2k+3+2r)}$
- Recursion relation for $r = -1$

  $a_{k+1} = -\frac{a_k}{(k+1)(2k+1)}$
- Solution for $r = -1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = -\frac{a_k}{(k+1)(2k+1)}\right]$
- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+1} = -\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+2)}$

- Solution for $r = -\frac{1}{2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = -\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{2}}\right), a_{k+1} = -\frac{a_k}{(k+1)(2k+1)}, b_{k+1} = -\frac{b_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

1.95 problem 97

Internal problem ID [8233]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 97
Date solved : `Monday, October 21, 2024 at 05:03:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$6x^2y'' + x(10 - x)\,y' - (2 + x)\,y = 0$$

1.95.1 Solved as second order ode using Kovacic algorithm

Time used: 0.389 (sec)

Writing the ode as

$$6x^2y'' + \left(-x^2 + 10x\right)y' + (-x - 2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6x^2 \\ B &= -x^2 + 10x \\ C &= -x - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 4x + 28}{144x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 + 4x + 28$$
$$t = 144x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 + 4x + 28}{144x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 174: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 2 \\
&= 0
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$
L = [1, 2]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{1}{144} + \frac{7}{36x^2} + \frac{1}{36x}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{6}
\end{aligned}
$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$
v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0
$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{12} + \frac{1}{6x} + \frac{1}{x^2} - \frac{2}{x^3} - \frac{2}{x^4} + \frac{28}{x^5} - \frac{56}{x^6} - \frac{272}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{12}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{12}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{144}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 + 4x + 28}{144x^2} \\ &= Q + \frac{R}{144x^2} \\ &= \left(\frac{1}{144}\right) + \left(\frac{4x + 28}{144x^2}\right) \\ &= \frac{1}{144} + \frac{4x + 28}{144x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 144 gives $\frac{1}{36}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{36}\right) - (0) \\ &= \frac{1}{36} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{12} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{36}}{\frac{1}{12}} - 0\right) &= \frac{1}{6} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{36}}{\frac{1}{12}} - 0\right) &= -\frac{1}{6} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 4x + 28}{144x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{12}$	$\frac{1}{6}$	$-\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= -\frac{1}{6} - \left(-\frac{1}{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{6x} + (-)\left(\frac{1}{12}\right) \\
&= -\frac{1}{6x} - \frac{1}{12} \\
&= -\frac{2 + x}{12x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{6x} - \frac{1}{12}\right)(0) + \left(\left(\frac{1}{6x^2}\right) + \left(-\frac{1}{6x} - \frac{1}{12}\right)^2 - \left(\frac{x^2 + 4x + 28}{144x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{6x} - \frac{1}{12}\right) dx} \\
&= \frac{e^{-\frac{x}{12}}}{x^{1/6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-x^2 + 10x}{6x^2} \, dx} \\
&= z_1 e^{\frac{x}{12} - \frac{5 \ln(x)}{6}} \\
&= z_1 \left(\frac{e^{\frac{x}{12}}}{x^{5/6}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+10x}{6x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x}{6}-\frac{5\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \mathrm{e}^{\frac{x}{6}-\frac{5\ln(x)}{3}} x^2 dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\int \mathrm{e}^{\frac{x}{6}-\frac{5\ln(x)}{3}} x^2 dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.95.2 Maple step by step solution

Let's solve
$6x^2\left(\frac{d}{dx}y'\right) + x(10-x)\, y' - (2+x)\, y = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d}{dx}y'$
- Isolate 2nd derivative
  $\frac{d}{dx}y' = \frac{(2+x)y}{6x^2} + \frac{(x-10)y'}{6x}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d}{dx}y' - \frac{(x-10)y'}{6x} - \frac{(2+x)y}{6x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- Define functions
  $\left[P_2(x) = -\frac{x-10}{6x}, P_3(x) = -\frac{2+x}{6x^2}\right]$
- $x \cdot P_2(x)$ is analytic at $x = 0$
  $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{5}{3}$
- $x^2 \cdot P_3(x)$ is analytic at $x = 0$
  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{3}$
- $x = 0$is a regular singular point
  Check to see if $x_0 = 0$ is a regular singular point
  $x_0 = 0$

- Multiply by denominators
  $6x^2\left(\frac{d}{dx}y'\right) - x(x-10)\,y' + (-x-2)\,y = 0$
- Assume series solution for y
  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions
- Convert $x^m \cdot y$ to series expansion for $m = 0..1$
  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k - m$
  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$
  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
- Shift index using $k- >k + 1 - m$
  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion
  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$
  Rewrite ODE with series expansions
  $2a_0(1+r)\,(-1+3r)\,x^r + \left(\sum_{k=1}^{\infty} (2a_k(k+r+1)\,(3k+3r-1) - a_{k-1}(k+r))\,x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$2(1+r)(-1+3r)=0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{-1, \frac{1}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$6(k+r+1)\left(k+r-\frac{1}{3}\right)a_k - a_{k-1}(k+r)=0$$

- Shift index using $k->k+1$

$$6(k+2+r)\left(k+\frac{2}{3}+r\right)a_{k+1} - a_k(k+r+1)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{a_k(k+r+1)}{2(k+2+r)(3k+2+3r)}$$

- Recursion relation for $r=-1$

$$a_{k+1}=\frac{a_k k}{2(k+1)(3k-1)}$$

- Solution for $r=-1$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1}=\frac{a_k k}{2(k+1)(3k-1)}\right]$$

- Recursion relation for $r=\frac{1}{3}$

$$a_{k+1}=\frac{a_k\left(k+\frac{4}{3}\right)}{2\left(k+\frac{7}{3}\right)(3k+3)}$$

- Solution for $r=\frac{1}{3}$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1}=\frac{a_k\left(k+\frac{4}{3}\right)}{2\left(k+\frac{7}{3}\right)(3k+3)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+1}=\frac{a_k k}{2(k+1)(3k-1)}, b_{k+1}=\frac{b_k\left(k+\frac{4}{3}\right)}{2\left(k+\frac{7}{3}\right)(3k+3)}\right]$$

1.96 problem 98

Internal problem ID [8234]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 98
Date solved : `Monday, October 21, 2024 at 05:03:59 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(3+4x)\,y''+x(11+4x)\,y'-(3+4x)\,y=0$$

1.96.1 Solved as second order ode using Kovacic algorithm

Time used: 0.379 (sec)

Writing the ode as

$$\left(4x^3+3x^2\right)y''+\left(4x^2+11x\right)y'+(-3-4x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^3+3x^2 \\ B &= 4x^2+11x \\ C &= -3-4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{48x^2 + 8x + 91}{4(4x^2 + 3x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 48x^2 + 8x + 91$$
$$t = 4(4x^2 + 3x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{48x^2 + 8x + 91}{4(4x^2 + 3x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 176: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(4x^2 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{3}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{28}{9\left(x + \frac{3}{4}\right)^2} + \frac{176}{27\left(x + \frac{3}{4}\right)} - \frac{176}{27x} + \frac{91}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{91}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{13}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{7}{6} \end{aligned}$$

For the pole at $x = -\frac{3}{4}$ let b be the coefficient of $\frac{1}{\left(x+\frac{3}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{28}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{4}{3} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading

coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{48x^2 + 8x + 91}{4\left(4x^2 + 3x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{48x^2 + 8x + 91}{4\left(4x^2 + 3x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{13}{6}$	$-\frac{7}{6}$
$-\frac{3}{4}$	2	0	$\frac{7}{3}$	$-\frac{4}{3}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{5}{2}\right) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)} + (-)(0) \\
&= -\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)} \\
&= \frac{-7-20x}{8x^2+6x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x^2 + a_1 x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(2) + 2\left(-\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)}\right)(2x+a_1) + \left(\left(\frac{7}{6x^2} + \frac{4}{3\left(x+\frac{3}{4}\right)^2}\right) + \left(-\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)}\right)^2 - \left(\frac{48x^2+8x}{4(4x^2+3
$$

$$
\frac{12a_1x - 8x + 32a_0 -}{x(3+4x)}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{a_0 = \frac{7}{48}, a_1 = \frac{2}{3}\right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x^2 + \frac{2}{3}x + \frac{7}{48}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 + \frac{2}{3}x + \frac{7}{48}\right) e^{\int \left(-\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)}\right) dx} \\
&= \left(x^2 + \frac{2}{3}x + \frac{7}{48}\right) e^{-\frac{4\ln(3+4x)}{3} - \frac{7\ln(x)}{6}} \\
&= \frac{x^2 + \frac{2}{3}x + \frac{7}{48}}{(3+4x)^{4/3} x^{7/6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x^2+11x}{4x^3+3x^2}\,dx} \\
&= z_1 e^{\frac{4\ln(3+4x)}{3}-\frac{11\ln(x)}{6}} \\
&= z_1\left(\frac{(3+4x)^{4/3}}{x^{11/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^2+\frac{2}{3}x+\frac{7}{48}}{x^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{4x^2+11x}{4x^3+3x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1\int \frac{e^{\frac{8\ln(3+4x)}{3}-\frac{11\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{\frac{8\ln(3+4x)}{3}-\frac{11\ln(x)}{3}}x^6}{\left(x^2+\frac{2}{3}x+\frac{7}{48}\right)^2}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1+c_2y_2 \\
&= c_1\left(\frac{x^2+\frac{2}{3}x+\frac{7}{48}}{x^3}\right)+c_2\left(\frac{x^2+\frac{2}{3}x+\frac{7}{48}}{x^3}\left(\int \frac{\mathrm{e}^{\frac{8\ln(3+4x)}{3}-\frac{11\ln(x)}{3}}x^6}{\left(x^2+\frac{2}{3}x+\frac{7}{48}\right)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.96.2 Maple step by step solution

Let's solve

$x^2(3+4x)\left(\frac{d}{dx}y'\right)+x(11+4x)\,y'-(3+4x)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=\frac{y}{x^2}-\frac{(11+4x)y'}{x(3+4x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(11+4x)y'}{x(3+4x)}-\frac{y}{x^2}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{11+4x}{x(3+4x)},P_3(x)=-\frac{1}{x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=\frac{11}{3}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=-1$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(3+4x)\left(\frac{d}{dx}y'\right)+x(11+4x)\,y'+(-3-4x)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y$ to series expansion for $m=0..1$

    $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

    $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(3+r)\,(-1+3r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+3)\,(3k+3r-1) + 4a_{k-1}(k+r)\,(k-2+r)\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(3+r)\,(-1+3r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{-3, \frac{1}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$3(k+r+3)\left(k+r-\frac{1}{3}\right) a_k + 4a_{k-1}(k+r)\,(k-2+r) = 0$$

- Shift index using $k->k+1$

$$3(k+4+r)\left(k+\frac{2}{3}+r\right) a_{k+1} + 4a_k(k+r+1)\,(k+r-1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{4a_k(k+r+1)(k+r-1)}{(k+4+r)(3k+2+3r)}$$

- Recursion relation for $r = -3$; series terminates at $k = 2$

$$a_{k+1} = -\frac{4a_k(k-2)(k-4)}{(k+1)(3k-7)}$$

- Apply recursion relation for $k = 0$

$$a_1 = \frac{32a_0}{7}$$

- Apply recursion relation for $k = 1$

$$a_2 = \frac{3a_1}{2}$$

- Express in terms of a_0

$$a_2 = \frac{48a_0}{7}$$

- Terminating series solution of the ODE for $r = -3$. Use reduction of order to find the second

$$y = a_0 \cdot \left(\frac{48}{7}x^2 + \frac{32}{7}x + 1\right)$$

- Recursion relation for $r=\frac{1}{3}$

  $a_{k+1}=-\frac{4a_k\left(k+\frac{4}{3}\right)\left(k-\frac{2}{3}\right)}{\left(k+\frac{13}{3}\right)(3k+3)}$
- Solution for $r=\frac{1}{3}$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1}=-\frac{4a_k\left(k+\frac{4}{3}\right)\left(k-\frac{2}{3}\right)}{\left(k+\frac{13}{3}\right)(3k+3)}\right]$
- Combine solutions and rename parameters

  $\left[y=a_0\cdot\left(\frac{48}{7}x^2+\frac{32}{7}x+1\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), b_{k+1}=-\frac{4b_k\left(k+\frac{4}{3}\right)\left(k-\frac{2}{3}\right)}{\left(k+\frac{13}{3}\right)(3k+3)}\right]$

1.97.1 Solved as second order ode using Kovacic algorithm

Time used: 0.225 (sec)

Writing the ode as

$$\left(6x^3+4x^2\right)y''+\left(11x^2+4x\right)y'+(x-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=6x^3+4x^2\\B&=11x^2+4x\\C&=x-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-35}{16\left(2+3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -35$$
$$t = 16(2+3x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{35}{16\left(2+3x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 178: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(2+3x)^2$. There is a pole at $x = -\frac{2}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{35}{144\left(x + \frac{2}{3}\right)^2}$$

For the pole at $x = -\frac{2}{3}$ let b be the coefficient of $\frac{1}{\left(x+\frac{2}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{35}{16\,(2+3x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{35}{144}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{35}{16\left(2+3x\right)^{2}}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-\frac{2}{3}$	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{7}{12}$	$\frac{5}{12}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{5}{12}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= \frac{5}{12} - \left(\frac{5}{12}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{5}{12\left(x+\frac{2}{3}\right)} + (-)\left(0\right) \\ &= \frac{5}{12\left(x+\frac{2}{3}\right)} \\ &= \frac{5}{8+12x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{5}{12\left(x + \frac{2}{3}\right)}\right)(0) + \left(\left(-\frac{5}{12\left(x + \frac{2}{3}\right)^2}\right) + \left(\frac{5}{12\left(x + \frac{2}{3}\right)}\right)^2 - \left(-\frac{35}{16\,(2+3x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{5}{12\left(x+\frac{2}{3}\right)} dx} \\
&= (2+3x)^{5/12}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{11x^2+4x}{6x^3+4x^2} \, dx} \\
&= z_1 e^{-\frac{\ln(x)}{2} - \frac{5\ln(2+3x)}{12}} \\
&= z_1 \left(\frac{1}{\sqrt{x}\,(2+3x)^{5/12}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{11x^2+4x}{6x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)-\frac{5\ln(2+3x)}{6}}}{(y_1)^2}\, dx \\
&= y_1 \left(2\,\mathrm{e}^{-\ln(x)-\frac{5\ln(2+3x)}{6}} x(2+3x)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{\sqrt{x}}\right) + c_2 \left(\frac{1}{\sqrt{x}} \left(2\,\mathrm{e}^{-\ln(x)-\frac{5\ln(2+3x)}{6}} x(2+3x)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.97.2 Maple step by step solution

Let's solve

$2x^2(2+3x)\left(\frac{d}{dx}y'\right) + x(4+11x)\,y' - (1-x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(x-1)y}{2x^2(2+3x)} - \frac{(4+11x)y'}{2x(2+3x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(4+11x)y'}{2x(2+3x)} + \frac{(x-1)y}{2x^2(2+3x)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{4+11x}{2x(2+3x)}, P_3(x) = \frac{x-1}{2x^2(2+3x)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\Bigg|_{x=0} = -\frac{1}{4}$

- $x = 0$is a regular singular point
  Check to see if x_0 is a regular singular point
  $x_0 = 0$

- Multiply by denominators
  $2x^2(2+3x)\left(\frac{d}{dx}y'\right) + x(4+11x)\,y' + (x-1)\,y = 0$
- Assume series solution for y
  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$
  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k-m$
  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$
  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
- Shift index using $k- >k+1-m$
  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$
  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
- Shift index using $k- >k+2-m$
  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions
  $a_0(1+2r)\,(-1+2r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+1)\,(2k+2r-1) + a_{k-1}(2k+2r-1)\,(3k-2+3r\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+2r)\,(-1+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation
  $4\left(k+r-\frac{1}{2}\right)\left(\left(\frac{3k}{2}+\frac{3r}{2}-1\right)a_{k-1}+a_k\left(k+r+\frac{1}{2}\right)\right)=0$
- Shift index using $k->k+1$
  $4\left(k+r+\frac{1}{2}\right)\left(\left(\frac{3k}{2}+\frac{1}{2}+\frac{3r}{2}\right)a_k+a_{k+1}\left(k+\frac{3}{2}+r\right)\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=-\frac{(3k+3r+1)a_k}{2k+3+2r}$
- Recursion relation for $r=-\frac{1}{2}$
  $a_{k+1}=-\frac{\left(3k-\frac{1}{2}\right)a_k}{2k+2}$
- Solution for $r=-\frac{1}{2}$
  $\left[y=\sum_{k=0}^{\infty}a_k x^{k-\frac{1}{2}}, a_{k+1}=-\frac{\left(3k-\frac{1}{2}\right)a_k}{2k+2}\right]$
- Recursion relation for $r=\frac{1}{2}$
  $a_{k+1}=-\frac{\left(3k+\frac{5}{2}\right)a_k}{2k+4}$
- Solution for $r=\frac{1}{2}$
  $\left[y=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}, a_{k+1}=-\frac{\left(3k+\frac{5}{2}\right)a_k}{2k+4}\right]$
- Combine solutions and rename parameters
  $\left[y=\left(\sum_{k=0}^{\infty}a_k x^{k-\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{1}{2}}\right), a_{k+1}=-\frac{\left(3k-\frac{1}{2}\right)a_k}{2k+2}, b_{k+1}=-\frac{\left(3k+\frac{5}{2}\right)b_k}{2k+4}\right]$

1.98 problem 100

Internal problem ID [8236]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 100
Date solved : `Monday, October 21, 2024 at 05:04:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(2+x)\,y''+5x(1-x)\,y'-(2-8x)\,y=0$$

1.98.1 Solved as second order ode using Kovacic algorithm

Time used: 0.957 (sec)

Writing the ode as

$$x^2(2+x)\,y''+\left(-5x^2+5x\right)y'+(8x-2)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2(2+x)\\B&=-5x^2+5x\\C&=8x-2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int\frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^2 - 126x + 21}{4(x^2 + 2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3x^2 - 126x + 21$$
$$t = 4(x^2 + 2x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^2 - 126x + 21}{4(x^2 + 2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 180: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{147}{16x} + \frac{147}{16\,(2+x)} + \frac{21}{16x^2} + \frac{285}{16\,(2+x)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{285}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{19}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{15}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 - 126x + 21}{4\,(x^2 + 2x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{3x^2-126x+21}{4\left(x^2+2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-2	2	0	$\frac{19}{4}$	$-\frac{15}{4}$
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=-\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right)\\
&= -\frac{1}{2}-\left(-\frac{9}{2}\right)\\
&= 4
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{15}{4\left(2+x\right)} - \frac{3}{4x} + (-)\left(0\right) \\ &= -\frac{15}{4\left(2+x\right)} - \frac{3}{4x} \\ &= -\frac{3(3x+1)}{2x\left(2+x\right)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(-\frac{15}{4\left(2+x\right)} - \frac{3}{4x}\right)\left(4x^3 + 3x^2a_3 + 2a_2x + a_1\right) + \left(\left(\frac{15}{4\left(2+x\right)^2} + \frac{3}{4x^2}\right) + \left(-\frac{}{4}\right.\right.$$

$$\frac{3(4+a_3)\,x^3 + (8a_2 + }{}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{40}, a_1 = \frac{1}{5}, a_2 = \frac{3}{2}, a_3 = -4\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 4x^3 + \frac{3}{2}x^2 + \frac{1}{5}x + \frac{1}{40}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x^4 - 4x^3 + \frac{3}{2}x^2 + \frac{1}{5}x + \frac{1}{40}\right) e^{\int \left(-\frac{15}{4(2+x)} - \frac{3}{4x}\right)dx} \\ &= \left(x^4 - 4x^3 + \frac{3}{2}x^2 + \frac{1}{5}x + \frac{1}{40}\right) e^{-\frac{15\ln(2+x)}{4} - \frac{3\ln(x)}{4}} \\ &= \frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40\left(2+x\right)^{15/4} x^{3/4}}\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5x^2+5x}{x^2(2+x)}\, dx} \\
&= z_1 e^{\frac{15\ln(2+x)}{4}-\frac{5\ln(x)}{4}} \\
&= z_1 \left(\frac{(2+x)^{15/4}}{x^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5x^2+5x}{x^2(2+x)}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{15\ln(2+x)}{2}-\frac{5\ln(x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{10x^{5/2}\sqrt{2+x}\left(8x^5\sqrt{x(2+x)} + 4200\ln\left(\frac{x+\sqrt{x(2+x)}}{x}\right)x^4 - 4200\ln\left(\frac{\sqrt{x(2+x)}-x}{x}\right)x^4 + 328x^4\sqrt{x(2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40x^2}\right) \\
&\quad + c_2\left(\frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40x^2}\left(\frac{10x^{5/2}\sqrt{2+x}\left(8x^5\sqrt{x(2+x)} + 4200\ln\left(\frac{x+\sqrt{x(2+x)}}{x}\right)x^4 - 420
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.98.2 Maple step by step solution

Let's solve

$x^2(2+x)\left(\frac{d}{dx}y'\right)+5x(1-x)\,y'-(2-8x)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{2(4x-1)y}{x^2(2+x)}+\frac{5(x-1)y'}{x(2+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'-\frac{5(x-1)y'}{x(2+x)}+\frac{2(4x-1)y}{x^2(2+x)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=-\frac{5(x-1)}{x(2+x)},P_3(x)=\frac{2(4x-1)}{x^2(2+x)}\right]$

- ◦ $(2+x)\cdot P_2(x)$ is analytic at $x=-2$

  $\left((2+x)\cdot P_2(x)\right)\Big|_{x=-2}=-\frac{15}{2}$

- ◦ $(2+x)^2\cdot P_3(x)$ is analytic at $x=-2$

  $\left((2+x)^2\cdot P_3(x)\right)\Big|_{x=-2}=0$

- ◦ $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-2$

- Multiply by denominators

  $x^2(2+x)\left(\frac{d}{dx}y'\right)-5x(x-1)\,y'+(8x-2)\,y=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

  $(u^3-4u^2+4u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(-5u^2+25u-30)\left(\frac{d}{du}y(u)\right)+(8u-18)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ◦ Shift index using $k->k-m$

$$u^{m} \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^{m} \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$$u^{m} \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_{k}(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^{m} \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^{m} \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

$$u^{m} \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_{k}(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^{m} \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$2a_{0}r(-17+2r)\, u^{-1+r} + \left(2a_{1}(1+r)\,(-15+2r) - a_{0}(4r^{2}-29r+18)\right) u^{r} + \left(\sum_{k=1}^{\infty} (2a_{k+1}(k+1+$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

$$2r(-17+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{17}{2}\right\}$$

- Each term must be 0

$$2a_{1}(1+r)\,(-15+2r) - a_{0}(4r^{2}-29r+18) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(-4a_{k}+a_{k-1}+4a_{k+1})\, k^{2} + \left((-8a_{k}+2a_{k-1}+8a_{k+1})\, r + 29a_{k} - 8a_{k-1} - 26a_{k+1}\right) k + (-4a_{k}+a$$

- Shift index using $k->k+1$

$$(-4a_{k+1}+a_{k}+4a_{k+2})\,(k+1)^{2} + \left((-8a_{k+1}+2a_{k}+8a_{k+2})\, r + 29a_{k+1} - 8a_{k} - 26a_{k+2}\right)(k+1)$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^{2}a_{k}-4k^{2}a_{k+1}+2kra_{k}-8kra_{k+1}+r^{2}a_{k}-4r^{2}a_{k+1}-6ka_{k}+21ka_{k+1}-6ra_{k}+21ra_{k+1}+8a_{k}+7a_{k+1}}{2(2k^{2}+4kr+2r^{2}-9k-9r-26)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{k^{2}a_{k}-4k^{2}a_{k+1}-6ka_{k}+21ka_{k+1}+8a_{k}+7a_{k+1}}{2(2k^{2}-9k-26)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_{k}u^{k}, a_{k+2} = -\frac{k^{2}a_{k}-4k^{2}a_{k+1}-6ka_{k}+21ka_{k+1}+8a_{k}+7a_{k+1}}{2(2k^{2}-9k-26)}, -30a_{1}-18a_{0} = 0\right]$$

- Revert the change of variables $u = 2+x$

$$\left[y = \sum_{k=0}^{\infty} a_k (2+x)^k, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 6k a_k + 21k a_{k+1} + 8a_k + 7a_{k+1}}{2(2k^2 - 9k - 26)}, -30a_1 - 18a_0 = 0\right]$$

- Recursion relation for $r = \frac{17}{2}$

$$a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 11k a_k - 47k a_{k+1} + \frac{117}{4} a_k - \frac{207}{2} a_{k+1}}{2(2k^2 + 25k + 42)}$$

- Solution for $r = \frac{17}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{17}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 11k a_k - 47k a_{k+1} + \frac{117}{4} a_k - \frac{207}{2} a_{k+1}}{2(2k^2 + 25k + 42)}, 38a_1 - \frac{121 a_0}{2} = 0\right]$$

- Revert the change of variables $u = 2 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (2+x)^{k+\frac{17}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 11k a_k - 47k a_{k+1} + \frac{117}{4} a_k - \frac{207}{2} a_{k+1}}{2(2k^2 + 25k + 42)}, 38a_1 - \frac{121 a_0}{2} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (2+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (2+x)^{k+\frac{17}{2}}\right), a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 6k a_k + 21k a_{k+1} + 8a_k + 7a_{k+1}}{2(2k^2 - 9k - 26)}, -30\right.$$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 101
Date solved : `Monday, October 21, 2024 at 05:04:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$8x^2\left(-x^2+1\right)y''+2x\left(-13x^2+1\right)y'+\left(-9x^2+1\right)y=0$$

1.99.1 Solved as second order ode using Kovacic algorithm

Time used: 0.404 (sec)

Writing the ode as

$$\left(-8x^4+8x^2\right)y''+\left(-26x^3+2x\right)y'+\left(-9x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-8x^4+8x^2\\B&=-26x^3+2x\\C&=-9x^2+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-7x^4 - 26x^2 - 15}{64 (x^3 - x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -7x^4 - 26x^2 - 15$$
$$t = 64(x^3 - x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-7x^4 - 26x^2 - 15}{64 (x^3 - x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 182: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(x^3 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{15}{64x^2} - \frac{1}{4(x+1)} - \frac{3}{16(x-1)^2} - \frac{3}{16(x+1)^2} + \frac{1}{4x-4}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x=-1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{4} \\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{4}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty=0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r=\frac{s}{t}=\frac{-7x^4-26x^2-15}{64\left(x^3-x\right)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{7}{64}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{7}{8} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{8}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{-7x^4-26x^2-15}{64\left(x^3-x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{8}$	$\frac{3}{8}$
1	2	0	$\frac{3}{4}$	$\frac{1}{4}$
-1	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{8}$	$\frac{1}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{7}{8} - \left(\frac{7}{8}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x - c_3}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{3}{8x} + \frac{1}{4x - 4} + \frac{1}{4x + 4} + (0) \\
&= \frac{3}{8x} + \frac{1}{4x - 4} + \frac{1}{4x + 4} \\
&= \frac{7x^2 - 3}{8x^3 - 8x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{3}{8x} + \frac{1}{4x - 4} + \frac{1}{4x + 4}\right)(0) + \left(\left(-\frac{3}{8x^2} - \frac{1}{4(x-1)^2} - \frac{1}{4(x+1)^2}\right) + \left(\frac{3}{8x} + \frac{1}{4x - 4} + \frac{1}{4x + 4}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{3}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right) dx} \\
&= x^{3/8} (x + 1)^{1/4} (x - 1)^{1/4}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-26x^3+2x}{-8x^4+8x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{8}-\frac{3\ln(x+1)}{4}-\frac{3\ln(x-1)}{4}} \\
&= z_1 \left(\frac{1}{x^{1/8}\,(x+1)^{3/4}\,(x-1)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{1/4}(x^2-1)^{1/4}}{(x+1)^{3/4}\,(x-1)^{3/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-26x^3+2x}{-8x^4+8x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{4}-\frac{3\ln(x+1)}{2}-\frac{3\ln(x-1)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{4}-\frac{3\ln(x+1)}{2}-\frac{3\ln(x-1)}{2}}\,(x+1)^{3/2}\,(x-1)^{3/2}}{\sqrt{x}\,\sqrt{x^2-1}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/4}(x^2-1)^{1/4}}{(x+1)^{3/4}\,(x-1)^{3/4}}\right) + c_2\left(\frac{x^{1/4}(x^2-1)^{1/4}}{(x+1)^{3/4}\,(x-1)^{3/4}}\left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{4}-\frac{3\ln(x+1)}{2}-\frac{3\ln(x-1)}{2}}\,(x+1)^{3/2}\,(x-1)^{3/2}}{\sqrt{x}\,\sqrt{x^2-1}}d
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.99.2 Maple step by step solution

Let's solve

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$8x^2(x^2-1)\left(\frac{d}{dx}y'\right)+2x(13x^2-1)\,y'+(9x^2-1)\,y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(8u^4-32u^3+40u^2-16u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(26u^3-78u^2+76u-24)\left(\frac{d}{du}y(u)\right)+(9u^2-18u+8)\,y$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

  ◦ Shift index using $k->k-m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..3$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..4$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-8a_0r(1+2r)\,u^{-1+r} + (-8a_1(1+r)\,(3+2r) + 4a_0(1+2r)\,(2+5r))\,u^r + (-8a_2(2+r)\,(5+2r)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$$-8r(1+2r) = 0$$
- Values of r that satisfy the indicial equation
$$r \in \left\{0, -\frac{1}{2}\right\}$$
- The coefficients of each power of u must be 0
$$[-8a_1(1+r)\,(3+2r) + 4a_0(1+2r)\,(2+5r) = 0, -8a_2(2+r)\,(5+2r) + 4a_1(3+2r)\,(7+5r) -$$
- Solve for the dependent coefficient(s)
$$\left\{a_1 = \frac{a_0\,(10r^2+9r+2)}{2(2r^2+5r+3)}, a_2 = \frac{a_0\,(34r^3+76r^2+41r+5)}{4(2r^3+11r^2+19r+10)}\right\}$$
- Each term in the series must be 0, giving the recursion relation
$$8(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\,k^2 + 2(8(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\,r + 18a_k - 7a_{k-2} + 9a_{k-1}$$
- Shift index using $k- >k+2$
$$8(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\,(k+2)^2 + 2(8(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\,r + 18a_{k+2} - 7a_k + 9$$
- Recursion relation that defines series solution to ODE
$$a_{k+3} = \frac{8k^2a_k - 32k^2a_{k+1} + 40k^2a_{k+2} + 16kra_k - 64kra_{k+1} + 80kra_{k+2} + 8r^2a_k - 32r^2a_{k+1} + 40r^2a_{k+2} + 18ka_k - 110ka_{k+1} + 196ka_{k+}}{8(2k^2+4kr+2r^2+13k+13r+21)}$$
- Recursion relation for $r = 0$
$$a_{k+3} = \frac{8k^2a_k - 32k^2a_{k+1} + 40k^2a_{k+2} + 18ka_k - 110ka_{k+1} + 196ka_{k+2} + 9a_k - 96a_{k+1} + 240a_{k+2}}{8(2k^2+13k+21)}$$
- Solution for $r = 0$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+18ka_k-110ka_{k+1}+196ka_{k+2}+9a_k-96a_{k+1}+240a_{k+2}}{8(2k^2+13k+21)}, a_1=\frac{a_0}{3}\right.$$

- Revert the change of variables $u=x+1$

1.100 problem 102

Internal problem ID [8238]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 102
Date solved : `Monday, October 21, 2024 at 05:04:05 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2+1)\,y''-2x(-x^2+2)\,y'+4y=0$$

1.100.1 Solved as second order ode using Kovacic algorithm

Time used: 0.400 (sec)

Writing the ode as

$$(x^4+x^2)\,y''+(2x^3-4x)\,y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2\\ B &= 2x^3-4x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-x^2 + 2}{(x^3 + x)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -x^2 + 2 \\
t &= (x^3 + x)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-x^2 + 2}{(x^3 + x)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 184: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 6 - 2\\ &= 4\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2} + \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} + \frac{7i}{4(x-i)} - \frac{7i}{4(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4>2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-x^2+2}{(x^3+x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	2	-1
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{+}+\alpha_{c_2}^{-}+\alpha_{c_3}^{-}\right) \\
&= 1-(1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{2}{x} - \frac{1}{2\,(x-i)} - \frac{1}{2\,(x+i)} + (-)\,(0) \\
&= \frac{2}{x} - \frac{1}{2\,(x-i)} - \frac{1}{2\,(x+i)} \\
&= \frac{x^2+2}{x^3+x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{2}{x} - \frac{1}{2\,(x-i)} - \frac{1}{2\,(x+i)}\right)(0) + \left(\left(-\frac{2}{x^2} + \frac{1}{2\,(x-i)^2} + \frac{1}{2\,(x+i)^2}\right) + \left(\frac{2}{x} - \frac{1}{2\,(x-i)} - \frac{1}{2\,(x+\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)}\right) dx} \\
&= \frac{x^2}{\sqrt{x^2+1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^3-4x}{x^4+x^2}\, dx} \\ &= z_1 e^{-\frac{3\ln\left(x^2+1\right)}{2}+2\ln(x)} \\ &= z_1\left(\frac{x^2}{\left(x^2+1\right)^{3/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^4}{\left(x^2+1\right)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3-4x}{x^4+x^2}\, dx}}{\left(y_1\right)^2}\, dx \\ &= y_1 \int \frac{e^{-3\ln\left(x^2+1\right)+4\ln(x)}}{\left(y_1\right)^2}\, dx \\ &= y_1\left(-\frac{\left(3x^2+1\right)\left(x^2+1\right)^3 \mathrm{e}^{-3\ln\left(x^2+1\right)+4\ln(x)}}{3x^7}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{x^4}{\left(x^2+1\right)^2}\right) + c_2\left(\frac{x^4}{\left(x^2+1\right)^2}\left(-\frac{\left(3x^2+1\right)\left(x^2+1\right)^3 \mathrm{e}^{-3\ln\left(x^2+1\right)+4\ln(x)}}{3x^7}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.100.2 Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d}{dx}y'\right)-2x(-x^2+2)\,y'+4y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{4y}{x^2(x^2+1)}-\frac{2(x^2-2)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{2(x^2-2)y'}{x(x^2+1)}+\frac{4y}{x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

  $\left[P_2(x)=\frac{2(x^2-2)}{x(x^2+1)}, P_3(x)=\frac{4}{x^2(x^2+1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=-4$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=4$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

$x^2(x^2+1)\left(\frac{d}{dx}y'\right)+2x(x^2-2)\,y'+4y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m\cdot y'$ to series expansion for $m=1..3$

  $x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

  $x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^m\cdot\left(\frac{d}{dx}y'\right)$ to series expansion for $m=2..4$

  $$x^m\cdot\left(\frac{d}{dx}y'\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$x^m\cdot\left(\frac{d}{dx}y'\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+r)\,(-4+r)\,x^r+a_1r(-3+r)\,x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(k+r-1)\,(k+r-4)+a_{k-2}(k-2+r)\,(\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+r)\,(-4+r)=0$$

- Values of r that satisfy the indicial equation

  $$r\in\{1,4\}$$

- Each term must be 0

  $$a_1r(-3+r)=0$$

- Solve for the dependent coefficient(s)

  $$a_1=0$$

- Each term in the series must be 0, giving the recursion relation

  $$(k+r-1)\,(a_k(k+r-4)+a_{k-2}(k-2+r))=0$$

- Shift index using $k->k+2$

  $$(k+r+1)\,(a_{k+2}(k-2+r)+a_k(k+r))=0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{a_k(k+r)}{k-2+r}$$

- Recursion relation for $r=1$

  $$a_{k+2}=-\frac{a_k(k+1)}{k-1}$$

- Solution for $r=1$

  $$\left[y=\sum_{k=0}^{\infty}a_kx^{k+1},a_{k+2}=-\frac{a_k(k+1)}{k-1},a_1=0\right]$$

- Recursion relation for $r=4$

  $$a_{k+2}=-\frac{a_k(k+4)}{k+2}$$

- Solution for $r=4$

  $$\left[y=\sum_{k=0}^{\infty}a_kx^{k+4},a_{k+2}=-\frac{a_k(k+4)}{k+2},a_1=0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+4}\right), a_{k+2} = -\frac{a_k(k+1)}{k-1}, a_1 = 0, b_{k+2} = -\frac{b_k(k+4)}{k+2}, b_1 = 0\right]$$

Time used: 0.348 (sec)

Writing the ode as

$$(x^3+3x)\,y''+(-x^2+2)\,y'-8xy=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^3+3x \\ B &= -x^2+2 \\ C &= -8x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{35x^4 + 74x^2 - 8}{4\left(x^3 + 3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 35x^4 + 74x^2 - 8$$
$$t = 4\left(x^3 + 3x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{35x^4 + 74x^2 - 8}{4\left(x^3 + 3x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 186: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{3}$ of order 2. There is a pole at $x = -i\sqrt{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{9x^2} + \frac{85}{144\left(x - i\sqrt{3}\right)^2} + \frac{85}{144\left(x + i\sqrt{3}\right)^2} - \frac{187i\sqrt{3}}{144\left(x - i\sqrt{3}\right)} + \frac{187i\sqrt{3}}{144\left(x + i\sqrt{3}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{2}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{2}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{3} \end{aligned}$$

For the pole at $x = i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{85}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{12} \end{aligned}$$

For the pole at $x = -i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{3}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{85}{144}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{12} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{12}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{35x^4 + 74x^2 - 8}{4\left(x^3 + 3x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{35}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{35x^4 + 74x^2 - 8}{4\left(x^3 + 3x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{2}{3}$	$\frac{1}{3}$
$i\sqrt{3}$	2	0	$\frac{17}{12}$	$-\frac{5}{12}$
$-i\sqrt{3}$	2	0	$\frac{17}{12}$	$-\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+ + \alpha_{c_3}^+\right) \\
&= \frac{7}{2} - \left(\frac{7}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{2}{3x} + \frac{17}{12\left(x-i\sqrt{3}\right)} + \frac{17}{12\left(x+i\sqrt{3}\right)} + (0) \\
&= \frac{2}{3x} + \frac{17}{12\left(x-i\sqrt{3}\right)} + \frac{17}{12\left(x+i\sqrt{3}\right)} \\
&= \frac{2}{3x} + \frac{17x}{6x^2+18}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{2}{3x} + \frac{17}{12\left(x-i\sqrt{3}\right)} + \frac{17}{12\left(x+i\sqrt{3}\right)}\right)(0) + \left(\left(-\frac{2}{3x^2} - \frac{17}{12\left(x-i\sqrt{3}\right)^2} - \frac{17}{12\left(x+i\sqrt{3}\right)^2}\right) + \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{3x} + \frac{17}{12\left(x - i\sqrt{3}\right)} + \frac{17}{12\left(x + i\sqrt{3}\right)}\right) dx} \\
&= x^{2/3} \left(x^2 + 3\right)^{17/12}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-x^2+2}{x^3+3x} \, dx} \\
&= z_1 e^{\frac{5 \ln\left(x^2+3\right)}{12} - \frac{\ln(x)}{3}} \\
&= z_1 \left(\frac{\left(x^2+3\right)^{5/12}}{x^{1/3}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \left(x^2 + 3\right)^{11/6} x^{1/3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^3+3x} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{5 \ln\left(x^2+3\right)}{6} - \frac{2 \ln(x)}{3}}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(-\frac{x^{1/3} (8x^4 + 44x^2 + 55) \, \mathrm{e}^{\frac{5 \ln\left(x^2+3\right)}{6} - \frac{2 \ln(x)}{3}}}{55 \left(x^2+3\right)^{8/3}}\right)
\end{aligned}$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1\left(\left(x^2+3\right)^{11/6} x^{1/3}\right)$$
$$+ c_2\left(\left(x^2+3\right)^{11/6} x^{1/3}\left(-\frac{x^{1/3}(8x^4+44x^2+55)\,\mathrm{e}^{\frac{5\ln\left(x^2+3\right)}{6}-\frac{2\ln(x)}{3}}}{55\left(x^2+3\right)^{8/3}}\right)\right)$$

Will add steps showing solving for IC soon.

1.101.2 Maple step by step solution

Let's solve

$x(x^2+3)\left(\frac{d}{dx}y'\right) + (-x^2+2)\,y' - 8xy = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{8y}{x^2+3} + \frac{(x^2-2)y'}{x(x^2+3)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{(x^2-2)y'}{x(x^2+3)} - \frac{8y}{x^2+3} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{x^2-2}{x(x^2+3)}, P_3(x) = -\frac{8}{x^2+3}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x=0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{2}{3}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x(x^2+3)\left(\frac{d}{dx}y'\right) + (-x^2+2)\,y' - 8xy = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

◦ Convert $x \cdot y$ to series expansion

$$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$$

◦ Shift index using $k->k-1$

$$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$

◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

◦ Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

◦ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 1..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

◦ Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+3r)\, x^{-1+r} + a_1(1+r)\,(2+3r)\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+r+1)\,(3k+2+3r) + a_{k-1}(k+r-$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-1+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, \frac{1}{3}\right\}$
- Each term must be 0
  $a_1(1+r)\,(2+3r) = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r+1)\left(a_{k-1}(k-5+r) + 3a_{k+1}\left(k+\frac{2}{3}+r\right)\right) = 0$
- Shift index using $k->k+1$
  $(k+r+2)\left(a_k(k+r-4) + 3a_{k+2}\left(k+\frac{5}{3}+r\right)\right) = 0$
- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{a_k(k+r-4)}{3k+5+3r}$

- Recursion relation for $r = 0$; series terminates at $k = 4$

  $a_{k+2} = -\frac{a_k(k-4)}{3k+5}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k-4)}{3k+5}, 2a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{3}$

  $a_{k+2} = -\frac{a_k\left(k-\frac{11}{3}\right)}{3k+6}$

- Solution for $r = \frac{1}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{a_k\left(k-\frac{11}{3}\right)}{3k+6}, 4a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{a_k(k-4)}{3k+5}, 2a_1 = 0, b_{k+2} = -\frac{b_k\left(k-\frac{11}{3}\right)}{3k+6}, 4b_1 = 0\right]$

Solve

$$4x^2\left(-x^2+1\right)y''+x\left(-19x^2+7\right)y'-\left(14x^2+1\right)y=0$$

1.102.1 Solved as second order ode using Kovacic algorithm

Time used: 0.392 (sec)

Writing the ode as

$$\left(-4x^4+4x^2\right)y''+\left(-19x^3+7x\right)y'+\left(-14x^2-1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-4x^4+4x^2\\B&=-19x^3+7x\\C&=-14x^2-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-15x^4 - 42x^2 + 9}{64\left(x^3 - x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -15x^4 - 42x^2 + 9$$
$$t = 64\left(x^3 - x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-15x^4 - 42x^2 + 9}{64\left(x^3 - x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 188: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(x^3 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16(x+1)^2} - \frac{3}{16(x-1)^2} + \frac{9}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{9}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{8} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-15x^4 - 42x^2 + 9}{64\left(x^3 - x\right)^2}
$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{15}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-15x^4 - 42x^2 + 9}{64\left(x^3 - x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{9}{8}$	$-\frac{1}{8}$
1	2	0	$\frac{3}{4}$	$\frac{1}{4}$
-1	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{8}$	$\frac{3}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{3}{8}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= \frac{3}{8} - \left(\frac{3}{8}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4} + (-)\left(0\right) \\ &= -\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4} \\ &= \frac{3x^2+1}{8x^3-8x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right)(0) + \left(\left(\frac{1}{8x^2} - \frac{1}{4\left(x-1\right)^2} - \frac{1}{4\left(x+1\right)^2}\right) + \left(-\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right) dx} \\ &= \frac{\left(x+1\right)^{1/4} \left(x-1\right)^{1/4}}{x^{1/8}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-19x^3+7x}{-4x^4+4x^2}\,dx} \\
&= z_1 e^{-\frac{7\ln(x)}{8}-\frac{3\ln(x+1)}{4}-\frac{3\ln(x-1)}{4}} \\
&= z_1\left(\frac{1}{x^{7/8}(x+1)^{3/4}(x-1)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(x^2-1)^{1/4}}{x(x+1)^{3/4}(x-1)^{3/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-19x^3+7x}{-4x^4+4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(x)}{4}-\frac{3\ln(x+1)}{2}-\frac{3\ln(x-1)}{2}}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{7\ln(x)}{4}-\frac{3\ln(x+1)}{2}-\frac{3\ln(x-1)}{2}}x^2(x+1)^{3/2}(x-1)^{3/2}}{\sqrt{x^2-1}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(\frac{(x^2-1)^{1/4}}{x(x+1)^{3/4}(x-1)^{3/4}}\right) + c_2\left(\frac{(x^2-1)^{1/4}}{x(x+1)^{3/4}(x-1)^{3/4}}\left(\int \frac{\mathrm{e}^{-\frac{7\ln(x)}{4}-\frac{3\ln(x+1)}{2}-\frac{3\ln(x-1)}{2}}x^2(x+1)^{3/2}(x-}{\sqrt{x^2-1}}\right.\right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.102.2 Maple step by step solution

Let's solve

$4x^2(-x^2+1)\left(\frac{d}{dx}y'\right)+x(-19x^2+7)\,y'-(14x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{(14x^2+1)y}{4x^2(x^2-1)}-\frac{(19x^2-7)y'}{4x(x^2-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{(19x^2-7)y'}{4x(x^2-1)}+\frac{(14x^2+1)y}{4x^2(x^2-1)}=0$

☐ Check to see if x_0 is a regular singular point

- ∘ Define functions

$\left[P_2(x)=\frac{19x^2-7}{4x(x^2-1)},P_3(x)=\frac{14x^2+1}{4x^2(x^2-1)}\right]$

- ∘ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

$\left((x+1)\cdot P_2(x)\right)\bigg|_{x=-1}=\frac{3}{2}$

- ∘ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$\left((x+1)^2\cdot P_3(x)\right)\bigg|_{x=-1}=0$

- ∘ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$4x^2(x^2-1)\left(\frac{d}{dx}y'\right)+x(19x^2-7)\,y'+(14x^2+1)\,y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(4u^4-16u^3+20u^2-8u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(19u^3-57u^2+50u-12)\left(\frac{d}{du}y(u)\right)+(14u^2-28u+15$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ∘ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

$u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ∘ Shift index using $k->k-m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..3$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..4$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-4a_0 r(1+2r)\, u^{-1+r} + \left(-4a_1(1+r)\,(3+2r) + 5a_0(4r^2+6r+3)\right) u^r + \left(-4a_2(2+r)\,(5+2r) +\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$$-4r(1+2r) = 0$$
- Values of r that satisfy the indicial equation
$$r \in \left\{0, -\frac{1}{2}\right\}$$
- The coefficients of each power of u must be 0
$$[-4a_1(1+r)\,(3+2r) + 5a_0(4r^2+6r+3) = 0, -4a_2(2+r)\,(5+2r) + 5a_1(4r^2+14r+13) - a_0$$
- Solve for the dependent coefficient(s)
$$\left\{a_1 = \frac{5a_0(4r^2+6r+3)}{4(2r^2+5r+3)}, a_2 = \frac{a_0(272r^4+1352r^3+2464r^2+1948r+639)}{16(4r^4+28r^3+71r^2+77r+30)}\right\}$$
- Each term in the series must be 0, giving the recursion relation
$$4(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\, k^2 + (8(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\, r + 30a_k - a_{k-2} - 9a_{k-1} -$$
- Shift index using $k- >k+2$
$$4(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\,(k+2)^2 + (8(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\, r + 30a_{k+2} - a_k - 9a_k$$
- Recursion relation that defines series solution to ODE
$$a_{k+3} = \frac{4k^2a_k - 16k^2a_{k+1} + 20k^2a_{k+2} + 8kra_k - 32kra_{k+1} + 40kra_{k+2} + 4r^2a_k - 16r^2a_{k+1} + 20r^2a_{k+2} + 15ka_k - 73ka_{k+1} + 110ka_{k+2}}{4(2k^2+4kr+2r^2+13k+13r+21)}$$
- Recursion relation for $r = 0$
$$a_{k+3} = \frac{4k^2a_k - 16k^2a_{k+1} + 20k^2a_{k+2} + 15ka_k - 73ka_{k+1} + 110ka_{k+2} + 14a_k - 85a_{k+1} + 155a_{k+2}}{4(2k^2+13k+21)}$$
- Solution for $r = 0$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+3}=\frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+15ka_k-73ka_{k+1}+110ka_{k+2}+14a_k-85a_{k+1}+155a_{k+2}}{4(2k^2+13k+21)}, a_1=\frac{5a}{4}\right.$$

- Revert the change of variables $u=x+1$

$$\left[y=\sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+3}=\frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+15ka_k-73ka_{k+1}+110ka_{k+2}+14a_k-85a_{k+1}+155a_{k+2}}{4(2k^2+13k+21)}, a_1=\right.$$

- Recursion relation for $r=-\frac{1}{2}$

$$a_{k+3}=\frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+11ka_k-57ka_{k+1}+90ka_{k+2}+\frac{15}{2}a_k-\frac{105}{2}a_{k+1}+105a_{k+2}}{4(2k^2+11k+15)}$$

- Solution for $r=-\frac{1}{2}$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k-\frac{1}{2}}, a_{k+3}=\frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+11ka_k-57ka_{k+1}+90ka_{k+2}+\frac{15}{2}a_k-\frac{105}{2}a_{k+1}+105a_{k+2}}{4(2k^2+11k+15)}, a_1=\right.$$

- Revert the change of variables $u=x+1$

$$\left[y=\sum_{k=0}^{\infty} a_k(x+1)^{k-\frac{1}{2}}, a_{k+3}=\frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+11ka_k-57ka_{k+1}+90ka_{k+2}+\frac{15}{2}a_k-\frac{105}{2}a_{k+1}+105a_{k+2}}{4(2k^2+11k+15)}, a\right.$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k(x+1)^k\right)+\left(\sum_{k=0}^{\infty} b_k(x+1)^{k-\frac{1}{2}}\right), a_{k+3}=\frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+15ka_k-73ka_{k+1}+110ka}{4(2k^2+13k+21)}\right.$$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 105
Date solved : `Monday, October 21, 2024 at 05:04:09 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2\left(-x^2+2\right)y''+x\left(-11x^2+1\right)y'+\left(-5x^2+1\right)y=0$$

1.103.1 Solved as second order ode using Kovacic algorithm

Time used: 0.431 (sec)

Writing the ode as

$$\left(-3x^4+6x^2\right)y''+\left(-11x^3+x\right)y'+\left(-5x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -3x^4+6x^2 \\ B &= -11x^3+x \\ C &= -5x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5x^4 - 4x^2 - 35}{36\left(x^3 - 2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -5x^4 - 4x^2 - 35$$
$$t = 36\left(x^3 - 2x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-5x^4 - 4x^2 - 35}{36\left(x^3 - 2x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 190: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^3 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \sqrt{2}$ of order 2. There is a pole at $x = -\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{35}{144x^2} - \frac{7}{64\left(x - \sqrt{2}\right)^2} - \frac{7}{64\left(x + \sqrt{2}\right)^2} + \frac{31\sqrt{2}}{384\left(x - \sqrt{2}\right)} - \frac{31\sqrt{2}}{384\left(x + \sqrt{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

For the pole at $x = \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = -\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+\sqrt{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-5x^4 - 4x^2 - 35}{36\left(x^3 - 2x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{5}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-5x^4 - 4x^2 - 35}{36\left(x^3 - 2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$
$\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$-\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= \frac{5}{6} - \left(\frac{5}{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x - c_3}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{7}{12x} + \frac{1}{8x - 8\sqrt{2}} + \frac{1}{8x + 8\sqrt{2}} + (0) \\ &= \frac{7}{12x} + \frac{1}{8x - 8\sqrt{2}} + \frac{1}{8x + 8\sqrt{2}} \\ &= \frac{5x^2 - 7}{6x^3 - 12x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{12x} + \frac{1}{8x - 8\sqrt{2}} + \frac{1}{8x + 8\sqrt{2}}\right)(0) + \left(\left(-\frac{7}{12x^2} - \frac{1}{8\left(x - \sqrt{2}\right)^2} - \frac{1}{8\left(x + \sqrt{2}\right)^2}\right) + \left(\frac{7}{12x} + \frac{}{8x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(\frac{7}{12x} + \frac{1}{8x - 8\sqrt{2}} + \frac{1}{8x + 8\sqrt{2}}\right) dx} \\ &= x^{7/12} \left(x + \sqrt{2}\right)^{1/8} \left(x - \sqrt{2}\right)^{1/8} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-11x^3+x}{-3x^4+6x^2}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{12}-\frac{7\ln\left(x^2-2\right)}{8}} \\
&= z_1 \left(\frac{1}{x^{1/12}\left(x^2-2\right)^{7/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\sqrt{x}}{\left(x^2-2\right)^{3/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-11x^3+x}{-3x^4+6x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{6}-\frac{7\ln\left(x^2-2\right)}{4}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{6}-\frac{7\ln\left(x^2-2\right)}{4}}\left(x^2-2\right)^{3/2}}{x} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x}}{\left(x^2-2\right)^{3/4}}\right) + c_2 \left(\frac{\sqrt{x}}{\left(x^2-2\right)^{3/4}}\left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{6}-\frac{7\ln\left(x^2-2\right)}{4}}\left(x^2-2\right)^{3/2}}{x} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.103.2 Maple step by step solution

Let's solve

$3x^2(-x^2+2)\left(\frac{d}{dx}y'\right)+x(-11x^2+1)\,y'+(-5x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{(5x^2-1)y}{3x^2(x^2-2)}-\frac{(11x^2-1)y'}{3x(x^2-2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{(11x^2-1)y'}{3x(x^2-2)}+\frac{(5x^2-1)y}{3x^2(x^2-2)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{11x^2-1}{3x(x^2-2)},P_3(x)=\frac{5x^2-1}{3x^2(x^2-2)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$\left.(x\cdot P_2(x))\right|_{x=0}=\frac{1}{6}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left.(x^2\cdot P_3(x))\right|_{x=0}=\frac{1}{6}$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$3x^2(x^2-2)\left(\frac{d}{dx}y'\right)+x(11x^2-1)\,y'+(5x^2-1)\,y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

$x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

$x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k- > k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(-1+3r)\,(-1+2r)\,x^r - a_1(2+3r)\,(1+2r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (-a_k(3k+3r-1)\,(2k+2r-1)+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$$-(-1+3r)\,(-1+2r) = 0$$
- Values of r that satisfy the indicial equation
$$r \in \left\{\frac{1}{2}, \frac{1}{3}\right\}$$
- Each term must be 0
$$-a_1(2+3r)\,(1+2r) = 0$$
- Solve for the dependent coefficient(s)
$$a_1 = 0$$
- Each term in the series must be 0, giving the recursion relation
$$-6\left(k+r-\frac{1}{3}\right)\left(\frac{(-k-r+1)a_{k-2}}{2} + a_k\left(k+r-\frac{1}{2}\right)\right) = 0$$
- Shift index using $k- > k+2$
$$-6\left(k+\frac{5}{3}+r\right)\left(\frac{(-k-1-r)a_k}{2} + a_{k+2}\left(k+\frac{3}{2}+r\right)\right) = 0$$
- Recursion relation that defines series solution to ODE
$$a_{k+2} = \frac{(k+r+1)a_k}{2k+3+2r}$$
- Recursion relation for $r = \frac{1}{2}$
$$a_{k+2} = \frac{\left(k+\frac{3}{2}\right)a_k}{2k+4}$$
- Solution for $r = \frac{1}{2}$
$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{\left(k+\frac{3}{2}\right)a_k}{2k+4}, a_1 = 0\right]$$

- Recursion relation for $r = \frac{1}{3}$

  $a_{k+2} = \frac{\left(k+\frac{4}{3}\right)a_k}{2k+\frac{11}{3}}$
- Solution for $r = \frac{1}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = \frac{\left(k+\frac{4}{3}\right)a_k}{2k+\frac{11}{3}}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = \frac{\left(k+\frac{3}{2}\right)a_k}{2k+4}, a_1 = 0, b_{k+2} = \frac{\left(k+\frac{4}{3}\right)b_k}{2k+\frac{11}{3}}, b_1 = 0\right]$

1.104 problem 106

Internal problem ID [8242]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 106
Date solved : `Monday, October 21, 2024 at 05:04:11 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(x^2+2\right)y''-x\left(-7x^2+12\right)y'+\left(3x^2+7\right)y=0$$

1.104.1 Solved as second order ode using Kovacic algorithm

Time used: 0.448 (sec)

Writing the ode as

$$\left(2x^4+4x^2\right)y''+\left(7x^3-12x\right)y'+\left(3x^2+7\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+4x^2 \\ B &= 7x^3-12x \\ C &= 3x^2+7 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3x^4 - 72x^2 + 128}{16\left(x^3 + 2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -3x^4 - 72x^2 + 128$$
$$t = 16\left(x^3 + 2x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3x^4 - 72x^2 + 128}{16\left(x^3 + 2x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 192: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2} + \frac{65}{64\left(x - i\sqrt{2}\right)^2} + \frac{65}{64\left(x + i\sqrt{2}\right)^2} + \frac{135i\sqrt{2}}{128\left(x - i\sqrt{2}\right)} - \frac{135i\sqrt{2}}{128\left(x + i\sqrt{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{65}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{8} \end{aligned}$$

For the pole at $x = -i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{65}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{8} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-3x^4 - 72x^2 + 128}{16\left(x^3 + 2x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-3x^4 - 72x^2 + 128}{16\left(x^3 + 2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	2	-1
$i\sqrt{2}$	2	0	$\frac{13}{8}$	$-\frac{5}{8}$
$-i\sqrt{2}$	2	0	$\frac{13}{8}$	$-\frac{5}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{3}{4} - \left(\frac{3}{4}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{2}{x} - \frac{5}{8\left(x-i\sqrt{2}\right)} - \frac{5}{8\left(x+i\sqrt{2}\right)} + (0) \\
&= \frac{2}{x} - \frac{5}{8\left(x-i\sqrt{2}\right)} - \frac{5}{8\left(x+i\sqrt{2}\right)} \\
&= \frac{2}{x} - \frac{5x}{4x^2+8}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{2}{x} - \frac{5}{8\left(x-i\sqrt{2}\right)} - \frac{5}{8\left(x+i\sqrt{2}\right)}\right)(0) + \left(\left(-\frac{2}{x^2} + \frac{5}{8\left(x-i\sqrt{2}\right)^2} + \frac{5}{8\left(x+i\sqrt{2}\right)^2}\right) + \left(\frac{2}{x} - \frac{}{8(}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{x} - \frac{5}{8\left(x - i\sqrt{2}\right)} - \frac{5}{8\left(x + i\sqrt{2}\right)}\right) dx} \\
&= \frac{x^2}{\left(x^2+2\right)^{5/8}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^3-12x}{2x^4+4x^2} \, dx} \\
&= z_1 e^{\frac{3\ln(x)}{2} - \frac{13\ln\left(x^2+2\right)}{8}} \\
&= z_1 \left(\frac{x^{3/2}}{\left(x^2+2\right)^{13/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{7/2}}{\left(x^2+2\right)^{9/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^3-12x}{2x^4+4x^2} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{3\ln(x) - \frac{13\ln\left(x^2+2\right)}{4}}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{3\ln(x) - \frac{13\ln\left(x^2+2\right)}{4}} \left(x^2+2\right)^{9/2}}{x^7} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{7/2}}{(x^2+2)^{9/4}} \right) + c_2 \left(\frac{x^{7/2}}{(x^2+2)^{9/4}} \left(\int \frac{e^{3\ln(x) - \frac{13\ln(x^2+2)}{4}} (x^2+2)^{9/2}}{x^7} dx \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.104.2 Maple step by step solution

Let's solve

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k + 2 - m + r)\,(k + 1 - m + r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1 + 2r)\,(-7 + 2r)\, x^r + a_1(1 + 2r)\,(-5 + 2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k + 2r - 1)\,(2k + 2r - 7) + a$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1 + 2r)\,(-7 + 2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{\frac{1}{2}, \frac{7}{2}\right\}$
- Each term must be 0
  $a_1(1 + 2r)\,(-5 + 2r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $4\left(\frac{a_{k-2}(k+r-1)}{2} + a_k\left(k + r - \frac{7}{2}\right)\right)\left(k + r - \frac{1}{2}\right) = 0$
- Shift index using $k- >k + 2$

$$4\left(\frac{a_k(k+r+1)}{2}+a_{k+2}\left(k-\frac{3}{2}+r\right)\right)\left(k+\frac{3}{2}+r\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{a_k(k+r+1)}{2k-3+2r}$$

- Recursion relation for $r=\frac{1}{2}$

$$a_{k+2}=-\frac{a_k\left(k+\frac{3}{2}\right)}{2k-2}$$

- Solution for $r=\frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}},a_{k+2}=-\frac{a_k\left(k+\frac{3}{2}\right)}{2k-2},a_1=0\right]$$

- Recursion relation for $r=\frac{7}{2}$

$$a_{k+2}=-\frac{a_k\left(k+\frac{9}{2}\right)}{2k+4}$$

- Solution for $r=\frac{7}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k+\frac{7}{2}},a_{k+2}=-\frac{a_k\left(k+\frac{9}{2}\right)}{2k+4},a_1=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{7}{2}}\right),a_{k+2}=-\frac{a_k\left(k+\frac{3}{2}\right)}{2k-2},a_1=0,b_{k+2}=-\frac{b_k\left(k+\frac{9}{2}\right)}{2k+4},b_1=0\right]$$

1.105 problem 107

Internal problem ID [8243]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 107
Date solved : `Monday, October 21, 2024 at 05:04:12 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(x^2+2)\,y''+x(7x^2+4)\,y'-(-3x^2+1)\,y=0$$

1.105.1 Solved as second order ode using Kovacic algorithm

Time used: 0.378 (sec)

Writing the ode as

$$(2x^4+4x^2)\,y''+(7x^3+4x)\,y'+(3x^2-1)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+4x^2 \\ B &= 7x^3+4x \\ C &= 3x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3x^2 + 24}{16\left(x^2 + 2\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -3x^2 + 24$$
$$t = 16\left(x^2 + 2\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3x^2 + 24}{16\left(x^2 + 2\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 194: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2+2)^2$. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{15}{64\left(x - i\sqrt{2}\right)^2} - \frac{15}{64\left(x + i\sqrt{2}\right)^2} - \frac{9i\sqrt{2}}{128\left(x - i\sqrt{2}\right)} + \frac{9i\sqrt{2}}{128\left(x + i\sqrt{2}\right)}
$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8}
\end{aligned}
$$

For the pole at $x = -i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x + i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 + 24}{16\left(x^2+2\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^2 + 24}{16\left(x^2+2\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$i\sqrt{2}$	2	0	$\frac{5}{8}$	$\frac{3}{8}$
$-i\sqrt{2}$	2	0	$\frac{5}{8}$	$\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{3}{4} - \left(\frac{3}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{3}{8\left(x + i\sqrt{2}\right)} + (0) \\
&= \frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{3}{8\left(x + i\sqrt{2}\right)} \\
&= \frac{3x}{4x^2 + 8}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{3}{8\left(x + i\sqrt{2}\right)}\right)(0) + \left(\left(-\frac{3}{8\left(x - i\sqrt{2}\right)^2} - \frac{3}{8\left(x + i\sqrt{2}\right)^2}\right) + \left(\frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{}{8(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{3}{8\left(x + i\sqrt{2}\right)} \right) dx} \\
&= \left(-x^2 - 2\right)^{3/8}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^3+4x}{2x^4+4x^2}\,dx} \\
&= z_1 e^{-\frac{5\ln\left(x^2+2\right)}{8}-\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{1}{\left(x^2+2\right)^{5/8}\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(-1)^{3/8}}{\left(x^2+2\right)^{1/4}\sqrt{x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^3+4x}{2x^4+4x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{5\ln\left(x^2+2\right)}{4}-\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\int -\mathrm{e}^{-\frac{5\ln\left(x^2+2\right)}{4}-\ln(x)}\sqrt{x^2+2}\,x(-1)^{1/4}\,dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{(-1)^{3/8}}{\left(x^2+2\right)^{1/4}\sqrt{x}}\right) + c_2\left(\frac{(-1)^{3/8}}{\left(x^2+2\right)^{1/4}\sqrt{x}}\left(\int -\mathrm{e}^{-\frac{5\ln\left(x^2+2\right)}{4}-\ln(x)}\sqrt{x^2+2}\,x(-1)^{1/4}\,dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.105.2 Maple step by step solution

Let's solve

$2x^2(x^2+2)\left(\frac{d}{dx}y'\right)+x(7x^2+4)\,y'-(-3x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(3x^2-1)y}{2x^2(x^2+2)}-\frac{(7x^2+4)y'}{2x(x^2+2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(7x^2+4)y'}{2x(x^2+2)}+\frac{(3x^2-1)y}{2x^2(x^2+2)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{7x^2+4}{2x(x^2+2)},P_3(x)=\frac{3x^2-1}{2x^2(x^2+2)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\Big|_{x=0}=1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\Big|_{x=0}=-\frac{1}{4}$

- ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2x^2(x^2+2)\left(\frac{d}{dx}y'\right)+x(7x^2+4)\,y'+(3x^2-1)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- ○ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- ○ Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)\,(-1+2r)\, x^r + a_1(3+2r)\,(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)\,(2k+2r-1) + a_{k-2}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)\,(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)\,(1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $4\left(\frac{a_{k-2}(k+r-1)}{2} + a_k\left(k+r+\frac{1}{2}\right)\right)\left(k+r-\frac{1}{2}\right) = 0$

- Shift index using $k->k+2$

  $4\left(\frac{a_k(k+r+1)}{2} + a_{k+2}\left(k+\frac{5}{2}+r\right)\right)\left(k+\frac{3}{2}+r\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+1)}{2k+5+2r}$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{2k+4}$

- Solution for $r = -\frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{2k+4}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{2}$

  $$a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+6}$$

- Solution for $r = \frac{1}{2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+6}, a_1 = 0\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{2k+4}, a_1 = 0, b_{k+2} = -\frac{b_k\left(k+\frac{3}{2}\right)}{2k+6}, b_1 = 0\right]$$

1.106 problem 108

Internal problem ID [8244]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 108
Date solved : `Monday, October 21, 2024 at 05:04:14 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(2x^2+1\right)y''+5x\left(6x^2+1\right)y'-\left(-40x^2+2\right)y=0$$

1.106.1 Solved as second order ode using Kovacic algorithm

Time used: 0.621 (sec)

Writing the ode as

$$\left(4x^4+2x^2\right)y''+\left(30x^3+5x\right)y'+\left(40x^2-2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+2x^2 \\ B &= 30x^3+5x \\ C &= 40x^2-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{20x^4 + 12x^2 + 21}{16\,(2x^3 + x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 20x^4 + 12x^2 + 21$$
$$t = 16(2x^3 + x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{20x^4 + 12x^2 + 21}{16\,(2x^3 + x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 196: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(2x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{21}{16x^2} + \frac{5}{16\left(x - \frac{i\sqrt{2}}{2}\right)^2} + \frac{5}{16\left(x + \frac{i\sqrt{2}}{2}\right)^2} + \frac{13i\sqrt{2}}{16\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{13i\sqrt{2}}{16\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4}\end{aligned}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4}\end{aligned}$$

For the pole at $x=-\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{20x^4+12x^2+21}{16\left(2x^3+x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{20x^4+12x^2+21}{16\left(2x^3+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= \frac{5}{4} - \left(\frac{5}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{7}{4x} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)} + (0) \\ &= \frac{7}{4x} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)} \\ &= \frac{10x^2+7}{8x^3+4x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{4x} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)}\right)(0) + \left(\left(-\frac{7}{4x^2} + \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)^2} + \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)^2}\right) + \left(\frac{7}{4x} - \right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{7}{4x} - \frac{1}{4\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x + \frac{i\sqrt{2}}{2}\right)}\right) dx} \\
&= \frac{2^{3/4} x^{7/4}}{2\left(2x^2+1\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{30x^3+5x}{4x^4+2x^2} \, dx} \\
&= z_1 e^{-\frac{5\ln\left(x\left(2x^2+1\right)\right)}{4}} \\
&= z_1 \left(\frac{1}{\left(2x^3+x\right)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{2^{3/4} x^{3/4}}{2\left(2x^2+1\right)^{5/4}\left(2x^3+x\right)^{1/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{30x^3+5x}{4x^4+2x^2} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{5\ln\left(2x^3+x\right)}{2}}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\int \frac{\left(2x^2+1\right)^{5/2}\sqrt{2}}{\left(2x^3+x\right)^2 x^{3/2}} dx\right)
\end{aligned}
$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$

$$= c_1 \left(\frac{2^{3/4} x^{3/4}}{2 \left(2x^2+1\right)^{5/4} \left(2x^3+x\right)^{1/4}}\right) + c_2 \left(\frac{2^{3/4} x^{3/4}}{2 \left(2x^2+1\right)^{5/4} \left(2x^3+x\right)^{1/4}} \left(\int \frac{\left(2x^2+1\right)^{5/2} \sqrt{2}}{\left(2x^3+x\right)^2 x^{3/2}} dx\right)\right)$$

Will add steps showing solving for IC soon.

1.106.2 Maple step by step solution

Let's solve

$2x^2(2x^2+1)\left(\frac{d}{dx}y'\right) + 5x(6x^2+1)\,y' - (-40x^2+2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(20x^2-1)y}{x^2(2x^2+1)} - \frac{5(6x^2+1)y'}{2x(2x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{5(6x^2+1)y'}{2x(2x^2+1)} + \frac{(20x^2-1)y}{x^2(2x^2+1)} = 0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{5(6x^2+1)}{2x(2x^2+1)}, P_3(x) = \frac{20x^2-1}{x^2(2x^2+1)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x=0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{5}{2}$

  - $x^2 \cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -1$

  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $2x^2(2x^2+1)\left(\frac{d}{dx}y'\right) + 5x(6x^2+1)\,y' + (40x^2-2)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k + 2 - m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(-1+2r)\, x^r + a_1(3+r)\,(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+2)\,(2k+2r-1) + 2a_{k-2}(k -\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-2, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+r)\,(1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $2(k+r+2)\left(a_{k-2}(2k+1+2r) + a_k\left(k+r-\frac{1}{2}\right)\right) = 0$

- Shift index using $k- >k + 2$

  $2(k+r+4)\left(a_k(2k+2r+5) + a_{k+2}\left(k+\frac{3}{2}+r\right)\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2a_k(2k+2r+5)}{2k+3+2r}$

- Recursion relation for $r = -2$

$a_{k+2} = -\frac{2a_k(2k+1)}{2k-1}$

- Solution for $r = -2$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{2a_k(2k+1)}{2k-1}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{2}$

$a_{k+2} = -\frac{2a_k(2k+6)}{2k+4}$

- Solution for $r = \frac{1}{2}$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{2a_k(2k+6)}{2k+4}, a_1 = 0\right]$

- Combine solutions and rename parameters

$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{2a_k(2k+1)}{2k-1}, a_1 = 0, b_{k+2} = -\frac{2b_k(2k+6)}{2k+4}, b_1 = 0\right]$

Solve

$$x\left(x^2+1\right)y''+\left(7x^2+4\right)y'+8xy=0$$

1.107.1 Solved as second order ode using Kovacic algorithm

Time used: 0.336 (sec)

Writing the ode as

$$\left(x^3+x\right)y''+\left(7x^2+4\right)y'+8xy=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^3+x \\ B &= 7x^2+4 \\ C &= 8x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^4 + 14x^2 + 8}{4\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3x^4 + 14x^2 + 8$$
$$t = 4\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^4 + 14x^2 + 8}{4\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 198: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 6 - 4 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{3}{16\,(x-i)^2} - \frac{3}{16\,(x+i)^2} + \frac{7i}{16\,(x-i)} - \frac{7i}{16\,(x+i)} + \frac{2}{x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{4}\\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^4+14x^2+8}{4\left(x^3+x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^4+14x^2+8}{4\left(x^3+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	2	-1
i	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-i$	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i} + (-)\,(0) \\
&= -\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i} \\
&= -\frac{1}{x} + \frac{x}{2x^2+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right)(0) + \left(\left(\frac{1}{x^2} - \frac{1}{4\,(x-i)^2} - \frac{1}{4\,(x+i)^2}\right) + \left(-\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right) dx} \\
&= \frac{\left(x^2+1\right)^{1/4}}{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^2+4}{x^3+x}\,dx} \\
&= z_1 e^{-\frac{3\ln\left(x^2+1\right)}{4}-2\ln(x)} \\
&= z_1\left(\frac{1}{\left(x^2+1\right)^{3/4} x^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{\sqrt{x^2+1}\,x^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^2+4}{x^3+x}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln\left(x^2+1\right)}{2}-4\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\frac{x^5}{\sqrt{x^2+1}} - \frac{x^3}{3\sqrt{x^2+1}} + \frac{4x^7}{\sqrt{x^2+1}} + \frac{8x^9}{3\sqrt{x^2+1}} + \frac{x\sqrt{x^2+1}}{2} - \frac{\operatorname{arcsinh}(x)}{2}\right. \\
&\quad \left. + \frac{\sqrt{x^2+1}\,x^3}{3} - \frac{4x^5\sqrt{x^2+1}}{3} - \frac{8x^7\sqrt{x^2+1}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{\sqrt{x^2+1}\,x^3}\right) + c_2\left(\frac{1}{\sqrt{x^2+1}\,x^3}\left(\frac{x^5}{\sqrt{x^2+1}} - \frac{x^3}{3\sqrt{x^2+1}} + \frac{4x^7}{\sqrt{x^2+1}} + \frac{8x^9}{3\sqrt{x^2+1}}\right.\right. \\
&\quad \left.\left. + \frac{x\sqrt{x^2+1}}{2} - \frac{\operatorname{arcsinh}(x)}{2} + \frac{\sqrt{x^2+1}\,x^3}{3} - \frac{4x^5\sqrt{x^2+1}}{3} - \frac{8x^7\sqrt{x^2+1}}{3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.107.2 Maple step by step solution

Let's solve

$x(x^2+1)\left(\frac{d}{dx}y'\right)+(7x^2+4)\,y'+8xy=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{8y}{x^2+1}-\frac{(7x^2+4)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{(7x^2+4)y'}{x(x^2+1)}+\frac{8y}{x^2+1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{7x^2+4}{x(x^2+1)},P_3(x)=\frac{8}{x^2+1}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=4$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=0$

  ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$x(x^2+1)\left(\frac{d}{dx}y'\right)+(7x^2+4)\,y'+8xy=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x\cdot y$ to series expansion

  $x\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+1}$

  ◦ Shift index using $k->k-1$

$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
- Shift index using $k->k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx} y'\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(3+r)\, x^{-1+r} + a_1(1+r)\,(4+r)\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+r+1)\,(k+r+4) + a_{k-1}(k+r+3)\,(k\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-3, 0\}$
- Each term must be 0

  $a_1(1+r)\,(4+r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k+r+1)\,(a_{k+1}(k+r+4) + a_{k-1}(k+r+3)) = 0$
- Shift index using $k->k+1$

  $(k+r+2)\,(a_{k+2}(k+5+r) + a_k(k+r+4)) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+4)}{k+5+r}$
- Recursion relation for $r = -3$

  $a_{k+2} = -\frac{a_k(k+1)}{k+2}$
- Solution for $r = -3$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-3}, a_{k+2} = -\frac{a_k(k+1)}{k+2}, -2a_1 = 0\right]$
- Recursion relation for $r = 0$

$a_{k+2} = -\frac{a_k(k+4)}{k+5}$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k+4)}{k+5}, 4a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-3}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+2} = -\frac{a_k(k+1)}{k+2}, -2a_1 = 0, b_{k+2} = -\frac{b_k(k+4)}{k+5}, 4b_1 = 0\right]$$

Solve

$$2x^2\left(x^2+1\right)y''+x\left(8x^2+3\right)y'-\left(-4x^2+3\right)y=0$$

1.108.1 Solved as second order ode using Kovacic algorithm

Time used: 0.384 (sec)

Writing the ode as

$$\left(2x^4+2x^2\right)y''+\left(8x^3+3x\right)y'+\left(4x^2-3\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+2x^2 \\ B &= 8x^3+3x \\ C &= 4x^2-3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{36x^2 + 21}{16\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 36x^2 + 21$$
$$t = 16\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{36x^2 + 21}{16\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 200: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 6 - 2\\ &= 4\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{21}{16x^2} - \frac{15}{64(x-i)^2} - \frac{15}{64(x+i)^2} + \frac{27i}{64(x-i)} - \frac{27i}{64(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}\end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8}\end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{36x^2 + 21}{16\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
i	2	0	$\frac{5}{8}$	$\frac{3}{8}$
$-i$	2	0	$\frac{5}{8}$	$\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = 0$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{-} + \alpha_{c_3}^{-}\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{3}{4x} + \frac{3}{8(x-i)} + \frac{3}{8(x+i)} + (0) \\
&= -\frac{3}{4x} + \frac{3}{8(x-i)} + \frac{3}{8(x+i)} \\
&= -\frac{3}{4x(x^2+1)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{4x} + \frac{3}{8(x-i)} + \frac{3}{8(x+i)}\right)(0) + \left(\left(\frac{3}{4x^2} - \frac{3}{8(x-i)^2} - \frac{3}{8(x+i)^2}\right) + \left(-\frac{3}{4x} + \frac{3}{8(x-i)} + \right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(-\frac{3}{4x} + \frac{3}{8(x-i)} + \frac{3}{8(x+i)}\right) dx} \\
&= \frac{(x^2+1)^{3/8}}{x^{3/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{8x^3+3x}{2x^4+2x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln(x)}{4}-\frac{5\ln\left(x^2+1\right)}{8}} \\
&= z_1\left(\frac{1}{x^{3/4}\left(x^2+1\right)^{5/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x^{3/2}\left(x^2+1\right)^{1/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8x^3+3x}{2x^4+2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln(x)}{2}-\frac{5\ln\left(x^2+1\right)}{4}}}{(y_1)^2}\,dx \\
&= y_1\left(\int \mathrm{e}^{-\frac{3\ln(x)}{2}-\frac{5\ln\left(x^2+1\right)}{4}} x^3\sqrt{x^2+1}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x^{3/2}\left(x^2+1\right)^{1/4}}\right) + c_2\left(\frac{1}{x^{3/2}\left(x^2+1\right)^{1/4}}\left(\int \mathrm{e}^{-\frac{3\ln(x)}{2}-\frac{5\ln\left(x^2+1\right)}{4}} x^3\sqrt{x^2+1}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.108.2 Maple step by step solution

Let's solve

$2x^2(x^2+1)\left(\frac{d}{dx}y'\right)+x(8x^2+3)\,y'-(-4x^2+3)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(4x^2-3)y}{2x^2(x^2+1)}-\frac{(8x^2+3)y'}{2x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(8x^2+3)y'}{2x(x^2+1)}+\frac{(4x^2-3)y}{2x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{8x^2+3}{2x(x^2+1)},P_3(x)=\frac{4x^2-3}{2x^2(x^2+1)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=\frac{3}{2}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=-\frac{3}{2}$

- ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2x^2(x^2+1)\left(\frac{d}{dx}y'\right)+x(8x^2+3)\,y'+(4x^2-3)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(2r+3)\,(-1+r)\, x^r + a_1(5+2r)\, r\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+3)\,(k+r-1) + 2a_{k-2}(k+r)\,(k$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(2r+3)\,(-1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{1, -\frac{3}{2}\right\}$$

- Each term must be 0

$$a_1(5+2r)\, r = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$2\left(\left(k+r+\frac{3}{2}\right) a_k + a_{k-2}(k+r)\right)(k+r-1) = 0$$

- Shift index using $k- >k+2$

$$2\left(\left(k+\frac{7}{2}+r\right) a_{k+2} + a_k(k+r+2)\right)(k+r+1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{2a_k(k+r+2)}{2k+7+2r}$$

- Recursion relation for $r = 1$

$$a_{k+2} = -\frac{2a_k(k+3)}{2k+9}$$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{2a_k(k+3)}{2k+9}, a_1 = 0\right]$$

- Recursion relation for $r = -\frac{3}{2}$

$a_{k+2} = -\frac{2a_k\left(k+\frac{1}{2}\right)}{2k+4}$

- Solution for $r = -\frac{3}{2}$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{3}{2}}, a_{k+2} = -\frac{2a_k\left(k+\frac{1}{2}\right)}{2k+4}, a_1 = 0\right]$

1.109 problem 111

Internal problem ID [8247]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 111
Date solved : `Monday, October 21, 2024 at 05:04:18 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2y'' + 3x\left(x^2+3\right)y' - \left(-5x^2+1\right)y = 0$$

1.109.1 Solved as second order ode using Kovacic algorithm

Time used: 0.351 (sec)

Writing the ode as

$$9x^2y'' + \left(3x^3+9x\right)y' + \left(5x^2-1\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= 3x^3+9x \\ C &= 5x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 8x^2 - 5}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 8x^2 - 5 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 8x^2 - 5}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 202: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 4\\ &= -2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{36} - \frac{2}{9} - \frac{5}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\ &= \sum_{i=0}^{1} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{6} - \frac{2}{3x} - \frac{7}{4x^3} - \frac{7}{x^5} - \frac{595}{16x^7} - \frac{889}{4x^9} - \frac{45647}{32x^{11}} - \frac{76811}{8x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{6}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{36}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^4 - 8x^2 - 5}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{x^2}{36} - \frac{2}{9}\right) + \left(-\frac{5}{36x^2}\right) \\ &= \frac{x^2}{36} - \frac{2}{9} - \frac{5}{36x^2}\end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{2}{9}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{2}{9}\right) - (0) \\ &= -\frac{2}{9}\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{6} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{2}{9}}{\frac{1}{6}} - 1\right) &= -\frac{7}{6} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{2}{9}}{\frac{1}{6}} - 1\right) &= \frac{1}{6}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 8x^2 - 5}{36x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{6}$	$-\frac{7}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{6}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{6} - \left(\frac{1}{6}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{6x} + (-)\left(\frac{x}{6}\right) \\
&= \frac{1}{6x} - \frac{x}{6} \\
&= \frac{1}{6x} - \frac{x}{6}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{1}{6x} - \frac{x}{6}\right)(0) + \left(\left(-\frac{1}{6x^2} - \frac{1}{6}\right) + \left(\frac{1}{6x} - \frac{x}{6}\right)^2 - \left(\frac{x^4 - 8x^2 - 5}{36x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{6x} - \frac{x}{6}\right) dx} \\
&= x^{1/6} \mathrm{e}^{-\frac{x^2}{12}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{3x^3 + 9x}{9x^2} \, dx} \\
&= z_1 e^{-\frac{x^2}{12} - \frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x^2}{12}}}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{e^{-\frac{x^2}{6}}}{x^{1/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3+9x}{9x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{6}-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\int e^{-\frac{x^2}{6}-\ln(x)} x^{2/3} e^{\frac{x^2}{3}}\, dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{-\frac{x^2}{6}}}{x^{1/3}}\right) + c_2 \left(\frac{e^{-\frac{x^2}{6}}}{x^{1/3}} \left(\int e^{-\frac{x^2}{6}-\ln(x)} x^{2/3} e^{\frac{x^2}{3}}\, dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.109.2 Maple step by step solution

Let's solve

$9x^2\left(\frac{d}{dx}y'\right) + 3x(x^2+3)\, y' - (-5x^2+1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(5x^2-1)y}{9x^2} - \frac{(x^2+3)y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(x^2+3)y'}{3x} + \frac{(5x^2-1)y}{9x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $$\left[P_2(x) = \frac{x^2+3}{3x}, P_3(x) = \frac{5x^2-1}{9x^2}\right]$$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $$(x \cdot P_2(x))\bigg|_{x=0} = 1$$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $$(x^2 \cdot P_3(x))\bigg|_{x=0} = -\frac{1}{9}$$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $$9x^2\left(\frac{d}{dx}y'\right) + 3x(x^2+3)\,y' + (5x^2-1)\,y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

  - Shift index using $k- > k-m$

    $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

  - Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

  - Shift index using $k- > k+1-m$

    $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

  - Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

    $$x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$$

    Rewrite ODE with series expansions

$$a_0(1+3r)(-1+3r)x^r + a_1(4+3r)(2+3r)x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(3k+3r+1)(3k+3r-1) + a_{k-2}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+3r)(-1+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{3}, \frac{1}{3}\right\}$
- Each term must be 0
  $a_1(4+3r)(2+3r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $(3k+3r-1)(3a_k k + 3a_k r + a_k + a_{k-2}) = 0$
- Shift index using $k- > k+2$
  $(3k+3r+5)(3a_{k+2}(k+2) + 3a_{k+2}r + a_{k+2} + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k}{3k+7+3r}$
- Recursion relation for $r = -\frac{1}{3}$
  $a_{k+2} = -\frac{a_k}{3k+6}$
- Solution for $r = -\frac{1}{3}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+2} = -\frac{a_k}{3k+6}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{3}$
  $a_{k+2} = -\frac{a_k}{3k+8}$
- Solution for $r = \frac{1}{3}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{a_k}{3k+8}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{a_k}{3k+6}, a_1 = 0, b_{k+2} = -\frac{b_k}{3k+8}, b_1 = 0\right]$

Solve

$$6x^2y'' + x(6x^2+1)\,y' + (9x^2+1)\,y = 0$$

1.110.1 Solved as second order ode using Kovacic algorithm

Time used: 0.439 (sec)

Writing the ode as

$$6x^2y'' + (6x^3+x)\,y' + (9x^2+1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6x^2 \\ B &= 6x^3 + x \\ C &= 9x^2 + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{36x^4 - 132x^2 - 35}{144x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 36x^4 - 132x^2 - 35$$
$$t = 144x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{36x^4 - 132x^2 - 35}{144x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 204: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 4 \\
&= -2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{4} - \frac{11}{12} - \frac{35}{144x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{11}{12x} - \frac{13}{12x^3} - \frac{143}{72x^5} - \frac{130}{27x^7} - \frac{17017}{1296x^9} - \frac{597961}{15552x^{11}} - \frac{11016863}{93312x^{13}} + \dots \quad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \quad (10)$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{36x^4 - 132x^2 - 35}{144x^2} \\ &= Q + \frac{R}{144x^2} \\ &= \left(\frac{x^2}{4} - \frac{11}{12}\right) + \left(-\frac{35}{144x^2}\right) \\ &= \frac{x^2}{4} - \frac{11}{12} - \frac{35}{144x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{11}{12}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{11}{12}\right) - (0) \\ &= -\frac{11}{12} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{11}{12}}{\frac{1}{2}} - 1\right) &&= -\frac{17}{12} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{11}{12}}{\frac{1}{2}} - 1\right) &&= \frac{5}{12}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{36x^4 - 132x^2 - 35}{144x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	$-\frac{17}{12}$	$\frac{5}{12}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{5}{12}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{5}{12} - \left(\frac{5}{12}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{5}{12x} + (-)\left(\frac{x}{2}\right) \\
&= \frac{5}{12x} - \frac{x}{2} \\
&= \frac{5}{12x} - \frac{x}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{5}{12x} - \frac{x}{2}\right)(0) + \left(\left(-\frac{5}{12x^2} - \frac{1}{2}\right) + \left(\frac{5}{12x} - \frac{x}{2}\right)^2 - \left(\frac{36x^4 - 132x^2 - 35}{144x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{5}{12x} - \frac{x}{2}\right) dx} \\
&= x^{5/12} \mathrm{e}^{-\frac{x^2}{4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{6x^3 + x}{6x^2} \, dx} \\
&= z_1 e^{-\frac{x^2}{4} - \frac{\ln(x)}{12}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x^2}{4}}}{x^{1/12}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = x^{1/3}e^{-\frac{x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6x^3+x}{6x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{2}-\frac{\ln(x)}{6}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{e^{-\frac{x^2}{2}-\frac{\ln(x)}{6}}e^{x^2}}{x^{2/3}}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{1/3}e^{-\frac{x^2}{2}}\right) + c_2\left(x^{1/3}e^{-\frac{x^2}{2}}\left(\int \frac{e^{-\frac{x^2}{2}-\frac{\ln(x)}{6}}e^{x^2}}{x^{2/3}}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.110.2 Maple step by step solution

Let's solve

$6x^2\left(\frac{d}{dx}y'\right) + x(6x^2+1)\,y' + (9x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(9x^2+1)y}{6x^2} - \frac{(6x^2+1)y'}{6x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(6x^2+1)y'}{6x} + \frac{(9x^2+1)y}{6x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- Define functions

  $\left[P_2(x) = \frac{6x^2+1}{6x}, P_3(x) = \frac{9x^2+1}{6x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = \frac{1}{6}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = \frac{1}{6}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $6x^2\left(\frac{d}{dx}y'\right) + x(6x^2+1)\, y' + (9x^2+1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+3r)\,(-1+2r)\,x^r + a_1(2+3r)\,(1+2r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-1)\,(2k+2r-1) + 3a\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$(-1+3r)\,(-1+2r) = 0$
- Values of r that satisfy the indicial equation
$r \in \left\{\frac{1}{2}, \frac{1}{3}\right\}$
- Each term must be 0
$a_1(2+3r)\,(1+2r) = 0$
- Solve for the dependent coefficient(s)
$a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
$6\left(\left(k+r-\frac{1}{3}\right)a_k + a_{k-2}\right)\left(k+r-\frac{1}{2}\right) = 0$
- Shift index using $k- >k+2$
$6\left(\left(k+\frac{5}{3}+r\right)a_{k+2} + a_k\right)\left(k+\frac{3}{2}+r\right) = 0$
- Recursion relation that defines series solution to ODE
$a_{k+2} = -\frac{3a_k}{3k+5+3r}$
- Recursion relation for $r = \frac{1}{2}$
$a_{k+2} = -\frac{3a_k}{3k+\frac{13}{2}}$
- Solution for $r = \frac{1}{2}$
$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{3a_k}{3k+\frac{13}{2}}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{3}$
$a_{k+2} = -\frac{3a_k}{3k+6}$
- Solution for $r = \frac{1}{3}$
$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{3a_k}{3k+6}, a_1 = 0\right]$
- Combine solutions and rename parameters
$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{3a_k}{3k+\frac{13}{2}}, a_1 = 0, b_{k+2} = -\frac{3b_k}{3k+6}, b_1 = 0\right]$

Internal problem ID [8249]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 113
Date solved : `Monday, October 21, 2024 at 05:04:21 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2\left(x^2+1\right)y''+3x\left(13x^2+3\right)y'-\left(-25x^2+1\right)y=0$$

1.111.1 Solved as second order ode using Kovacic algorithm

Time used: 0.381 (sec)

Writing the ode as

$$\left(9x^4+9x^2\right)y''+\left(39x^3+9x\right)y'+\left(25x^2-1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^4+9x^2 \\ B &= 39x^3+9x \\ C &= 25x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9x^4 + 6x^2 - 5}{36\,(x^3 + x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -9x^4 + 6x^2 - 5$$
$$t = 36\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-9x^4 + 6x^2 - 5}{36\,(x^3 + x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 206: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{36(x-i)^2} - \frac{5}{36(x+i)^2} - \frac{i}{12(x-i)} + \frac{i}{12x+12i} - \frac{5}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{5}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{5}{6} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{6}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-9x^4+6x^2-5}{36\left(x^3+x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-9x^4+6x^2-5}{36\left(x^3+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{6}$	$\frac{1}{6}$
i	2	0	$\frac{5}{6}$	$\frac{1}{6}$
$-i$	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i} + (-)\,(0) \\
&= \frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i} \\
&= \frac{1}{6x} + \frac{x}{3x^2+3}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i}\right)(0) + \left(\left(-\frac{1}{6x^2} - \frac{1}{6\left(x-i\right)^2} - \frac{1}{6\left(x+i\right)^2}\right) + \left(\frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i}\right) dx} \\
&= \left(x^2+1\right)^{1/6} (-x)^{1/6}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{39x^3+9x}{9x^4+9x^2}\,dx} \\
&= z_1 e^{-\frac{5\ln\left(x^2+1\right)}{6}-\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{1}{\left(x^2+1\right)^{5/6}\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(-x)^{1/6}}{\left(x^2+1\right)^{2/3}\sqrt{x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{39x^3+9x}{9x^4+9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{5\ln\left(x^2+1\right)}{3}-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{5\ln\left(x^2+1\right)}{3}-\ln(x)}\left(x^2+1\right)^{4/3}x}{(-x)^{1/3}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(\frac{(-x)^{1/6}}{\left(x^2+1\right)^{2/3}\sqrt{x}}\right) + c_2\left(\frac{(-x)^{1/6}}{\left(x^2+1\right)^{2/3}\sqrt{x}}\left(\int \frac{\mathrm{e}^{-\frac{5\ln\left(x^2+1\right)}{3}-\ln(x)}\left(x^2+1\right)^{4/3}x}{(-x)^{1/3}}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.111.2 Maple step by step solution

Let's solve

$9x^2(x^2+1)\left(\frac{d}{dx}y'\right)+3x(13x^2+3)\,y'-(-25x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{(25x^2-1)y}{9x^2(x^2+1)}-\frac{(13x^2+3)y'}{3x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{(13x^2+3)y'}{3x(x^2+1)}+\frac{(25x^2-1)y}{9x^2(x^2+1)}=0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

$\left[P_2(x)=\frac{13x^2+3}{3x(x^2+1)},P_3(x)=\frac{25x^2-1}{9x^2(x^2+1)}\right]$

- ○ $x\cdot P_2(x)$ is analytic at $x=0$

$(x\cdot P_2(x))\bigg|_{x=0}=1$

- ○ $x^2\cdot P_3(x)$ is analytic at $x=0$

$(x^2\cdot P_3(x))\bigg|_{x=0}=-\frac{1}{9}$

- ○ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$9x^2(x^2+1)\left(\frac{d}{dx}y'\right)+3x(13x^2+3)\,y'+(25x^2-1)\,y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m\cdot y$ to series expansion for $m=0..2$

$x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ○ Shift index using $k->k-m$

$x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ○ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+3r)\,(-1+3r)\, x^r + a_1(4+3r)\,(2+3r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r+1)\,(3k+3r-1) + a_{k-2}\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(1+3r)\,(-1+3r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{-\frac{1}{3}, \frac{1}{3}\right\}$$

- Each term must be 0

$$a_1(4+3r)\,(2+3r) = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$9\left(\left(k+r-\frac{1}{3}\right) a_{k-2} + a_k\left(k+r+\frac{1}{3}\right)\right)\left(k+r-\frac{1}{3}\right) = 0$$

- Shift index using $k- >k+2$

$$9\left(\left(k+\frac{5}{3}+r\right) a_k + a_{k+2}\left(k+\frac{7}{3}+r\right)\right)\left(k+\frac{5}{3}+r\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{(3k+3r+5)a_k}{3k+7+3r}$$

- Recursion relation for $r = -\frac{1}{3}$

$$a_{k+2} = -\frac{(3k+4)a_k}{3k+6}$$

- Solution for $r = -\frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+2} = -\frac{(3k+4)a_k}{3k+6}, a_1 = 0\right]$$

- Recursion relation for $r = \frac{1}{3}$

$a_{k+2} = -\frac{(3k+6)a_k}{3k+8}$

- Solution for $r = \frac{1}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{(3k+6)a_k}{3k+8}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{(3k+4)a_k}{3k+6}, a_1 = 0, b_{k+2} = -\frac{(3k+6)b_k}{3k+8}, b_1 = 0\right]$

1.112 problem 114

Internal problem ID [8250]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 114
Date solved : `Monday, October 21, 2024 at 05:04:22 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+1\right)y''+4x\left(6x^2+1\right)y'-\left(-25x^2+1\right)y=0$$

1.112.1 Solved as second order ode using Kovacic algorithm

Time used: 0.337 (sec)

Writing the ode as

$$\left(4x^4+4x^2\right)y''+\left(24x^3+4x\right)y'+\left(25x^2-1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+4x^2 \\ B &= 24x^3+4x \\ C &= 25x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^2 - 6}{4(x^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -x^2 - 6$$
$$t = 4(x^2+1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^2 - 6}{4(x^2+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 208: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16\,(x-i)^2} + \frac{5}{16\,(x+i)^2} + \frac{7i}{16\,(x-i)} - \frac{7i}{16\,(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 6}{4\,(x^2+1)^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-x^2-6}{4\left(x^2+1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
i	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-i$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right)\\
&= \frac{1}{2} - \left(-\frac{1}{2}\right)\\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{4\left(x-i\right)} - \frac{1}{4\left(x+i\right)} + \left(-\right)\left(0\right) \\
&= -\frac{1}{4\left(x-i\right)} - \frac{1}{4\left(x+i\right)} \\
&= -\frac{x}{2x^2+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{4\left(x-i\right)} - \frac{1}{4\left(x+i\right)}\right)(1) + \left(\left(\frac{1}{4\left(x-i\right)^2} + \frac{1}{4\left(x+i\right)^2}\right) + \left(-\frac{1}{4\left(x-i\right)} - \frac{1}{4\left(x+i\right)}\right)^2 - \left(\frac{-}{4(\cdots}\right.\right.
$$

$$
\frac{(x^2+1\cdots}{(-x+i)^2(\cdots}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, e^{\int \left(-\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right) dx} \\
&= (x)\, \frac{1}{\left(\left(-x+i\right)\left(x+i\right)\right)^{1/4}} \\
&= \frac{x}{\left(-x^2-1\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{24x^3+4x}{4x^4+4x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}-\frac{5\ln\left(x^2+1\right)}{4}} \\
&= z_1\left(\frac{1}{\sqrt{x}\,\left(x^2+1\right)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(\frac{1}{2}-\frac{i}{2}\right)\sqrt{x}\,\sqrt{2}}{\left(x^2+1\right)^{3/2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{24x^3+4x}{4x^4+4x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)-\frac{5\ln\left(x^2+1\right)}{2}}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(i\left(-\frac{\left(x^2+1\right)^{3/2}}{x}+x\sqrt{x^2+1}+\operatorname{arcsinh}(x)\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\left(\frac{1}{2}-\frac{i}{2}\right)\sqrt{x}\,\sqrt{2}}{\left(x^2+1\right)^{3/2}}\right) \\
&\quad + c_2\left(\frac{\left(\frac{1}{2}-\frac{i}{2}\right)\sqrt{x}\,\sqrt{2}}{\left(x^2+1\right)^{3/2}}\left(i\left(-\frac{\left(x^2+1\right)^{3/2}}{x}+x\sqrt{x^2+1}+\operatorname{arcsinh}(x)\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.112.2 Maple step by step solution

Let's solve

$4x^2(x^2+1)\left(\frac{d}{dx}y'\right)+4x(6x^2+1)\,y'-(-25x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(25x^2-1)y}{4x^2(x^2+1)}-\frac{(6x^2+1)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(6x^2+1)y'}{x(x^2+1)}+\frac{(25x^2-1)y}{4x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

```

$$y(x) \to \frac{c_2 x \operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right) - c_2\sqrt{x^2+1} + c_1 x}{\sqrt{x}\,(x^2+1)^{3/2}}$$

1.113 problem 115

Internal problem ID [8251]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 115
Date solved : `Monday, October 21, 2024 at 05:04:23 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$8x^2(2x^2+1)\,y''+2x(34x^2+5)\,y'-(-30x^2+1)\,y=0$$

1.113.1 Solved as second order ode using Kovacic algorithm

Time used: 0.558 (sec)

Writing the ode as

$$(16x^4+8x^2)\,y''+(68x^3+10x)\,y'+(30x^2-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 16x^4+8x^2 \\ B &= 68x^3+10x \\ C &= 30x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{132x^4 + 148x^2 - 7}{64\left(2x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 132x^4 + 148x^2 - 7 \\ t &= 64\left(2x^3 + x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{132x^4 + 148x^2 - 7}{64\left(2x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 210: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(2x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64x^2} - \frac{3}{16\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{3}{16\left(x + \frac{i\sqrt{2}}{2}\right)^2} - \frac{i\sqrt{2}}{2\left(x - \frac{i\sqrt{2}}{2}\right)} + \frac{i\sqrt{2}}{2x + i\sqrt{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{132x^4 + 148x^2 - 7}{64\left(2x^3 + x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{33}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{8} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{132x^4 + 148x^2 - 7}{64\left(2x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = \frac{11}{8}$ then

$$\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{-} + \alpha_{c_3}^{-}\right) \\
&= \frac{11}{8} - \left(\frac{11}{8}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{7}{8x} + \frac{1}{4x-2i\sqrt{2}} + \frac{1}{4x+2i\sqrt{2}} + (0) \\
&= \frac{7}{8x} + \frac{1}{4x-2i\sqrt{2}} + \frac{1}{4x+2i\sqrt{2}} \\
&= \frac{22x^2+7}{16x^3+8x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{8x} + \frac{1}{4x-2i\sqrt{2}} + \frac{1}{4x+2i\sqrt{2}}\right)(0) + \left(\left(-\frac{7}{8x^2} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)^2} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)^2}\right) + \left(\frac{7}{8x} + \frac{}{4x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{7}{8x} + \frac{1}{4x - 2i\sqrt{2}} + \frac{1}{4x + 2i\sqrt{2}}\right) dx} \\
&= 2^{1/4} \left(2x^2 + 1\right)^{1/4} x^{7/8}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{68x^3 + 10x}{16x^4 + 8x^2} \, dx} \\
&= z_1 e^{-\frac{3 \ln\left(2x^2+1\right)}{4} - \frac{5 \ln(x)}{8}} \\
&= z_1 \left(\frac{1}{\left(2x^2 + 1\right)^{3/4} x^{5/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{1/4} 2^{1/4}}{\sqrt{2x^2 + 1}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{68x^3 + 10x}{16x^4 + 8x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{3 \ln\left(2x^2+1\right)}{2} - \frac{5 \ln(x)}{4}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{3 \ln\left(2x^2+1\right)}{2} - \frac{5 \ln(x)}{4}} \left(2x^2 + 1\right) \sqrt{2}}{2\sqrt{x}} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/4}2^{1/4}}{\sqrt{2x^2+1}}\right) + c_2\left(\frac{x^{1/4}2^{1/4}}{\sqrt{2x^2+1}}\left(\int \frac{\mathrm{e}^{-\frac{3\ln\left(2x^2+1\right)}{2}-\frac{5\ln(x)}{4}}\left(2x^2+1\right)\sqrt{2}}{2\sqrt{x}}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.113.2 Maple step by step solution

Let's solve

$8x^2(2x^2+1)\left(\frac{d}{dx}y'\right)+2x(34x^2+5)\,y'-(-30x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(30x^2-1)y}{8x^2(2x^2+1)}-\frac{(34x^2+5)y'}{4x(2x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(34x^2+5)y'}{4x(2x^2+1)}+\frac{(30x^2-1)y}{8x^2(2x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{34x^2+5}{4x(2x^2+1)},P_3(x)=\frac{30x^2-1}{8x^2(2x^2+1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\Big|_{x=0}=\frac{5}{4}$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\Big|_{x=0}=-\frac{1}{8}$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $8x^2(2x^2+1)\left(\frac{d}{dx}y'\right)+2x(34x^2+5)\,y'+(30x^2-1)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx} y'\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k + 2 - m$

$$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+2r)\,(-1+4r)\, x^r + a_1(3+2r)\,(3+4r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)\,(4k+4r-1) + 2a_{k-}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(1+2r)\,(-1+4r) = 0$

- Values of r that satisfy the indicial equation

$r \in \left\{-\frac{1}{2}, \frac{1}{4}\right\}$

- Each term must be 0

$a_1(3+2r)\,(3+4r) = 0$

- Solve for the dependent coefficient(s)

$a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

$8\left(k+r+\frac{1}{2}\right)\left(\left(2k+2r-\frac{5}{2}\right) a_{k-2} + a_k\left(k+r-\frac{1}{4}\right)\right) = 0$

- Shift index using $k- >k + 2$

$8\left(k+\frac{5}{2}+r\right)\left(\left(2k+\frac{3}{2}+2r\right) a_k + a_{k+2}\left(k+\frac{7}{4}+r\right)\right) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{2(4k+4r+3)a_k}{4k+7+4r}$

- Recursion relation for $r = -\frac{1}{2}$

$a_{k+2} = -\frac{2(4k+1)a_k}{4k+5}$

- Solution for $r = -\frac{1}{2}$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{2(4k+1)a_k}{4k+5}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{4}$

$a_{k+2} = -\frac{2(4k+4)a_k}{4k+8}$

- Solution for $r = \frac{1}{4}$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+2} = -\frac{2(4k+4)a_k}{4k+8}, a_1 = 0\right]$

- Combine solutions and rename parameters

$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{4}}\right), a_{k+2} = -\frac{2(4k+1)a_k}{4k+5}, a_1 = 0, b_{k+2} = -\frac{2(4k+4)b_k}{4k+8}, b_1 = 0\right]$

1.114 problem 116

Internal problem ID [8252]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 116
Date solved : `Monday, October 21, 2024 at 05:04:25 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(1+x)\,y''-x(1-3x)\,y'+y=0$$

1.114.1 Solved as second order ode using Kovacic algorithm

Time used: 0.206 (sec)

Writing the ode as

$$\left(2x^3+2x^2\right)y''+\left(3x^2-x\right)y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+2x^2\\ B &= 3x^2-x\\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -3$$
$$t = 16x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{3}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 212: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{3}{16x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{3}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{4} - \left(\frac{1}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{4x} + (-)(0) \\ &= \frac{1}{4x} \\ &= \frac{1}{4x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{4x}\right)(0) + \left(\left(-\frac{1}{4x^2}\right) + \left(\frac{1}{4x}\right)^2 - \left(-\frac{3}{16x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \frac{1}{4x} dx} \\
&= x^{1/4}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^2 - x}{2x^3 + 2x^2}\, dx} \\
&= z_1 e^{-\ln(1+x) + \frac{\ln(x)}{4}} \\
&= z_1 \left(\frac{x^{1/4}}{1+x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{1+x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{3x^2-x}{2x^3+2x^2}\,dx}}{(y_1)^2}\,dx$$
$$= y_1 \int \frac{e^{-2\ln(1+x)+\frac{\ln(x)}{2}}}{(y_1)^2}\,dx$$
$$= y_1\left(2\,\mathrm{e}^{-2\ln(1+x)+\frac{\ln(x)}{2}}(1+x)^2\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1\left(\frac{\sqrt{x}}{1+x}\right) + c_2\left(\frac{\sqrt{x}}{1+x}\left(2\,\mathrm{e}^{-2\ln(1+x)+\frac{\ln(x)}{2}}(1+x)^2\right)\right)$$

Will add steps showing solving for IC soon.

1.114.2 Maple step by step solution

Let's solve

$2x^2(1+x)\left(\frac{d}{dx}y'\right) - x(1-3x)\,y' + y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{2x^2(1+x)} - \frac{(3x-1)y'}{2x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(3x-1)y'}{2x(1+x)} + \frac{y}{2x^2(1+x)} = 0$

□ Check to see if x_0 is a regular singular point

  ○ Define functions

    $\left[P_2(x) = \frac{3x-1}{2x(1+x)}, P_3(x) = \frac{1}{2x^2(1+x)}\right]$

  ○ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

    $\left.\left((1+x)\cdot P_2(x)\right)\right|_{x=-1} = 2$

  ○ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

$$\left((1+x)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$$

- ○ $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- • Multiply by denominators

  $2x^2(1+x)\left(\frac{d}{dx}y'\right) + x(3x-1)\,y' + y = 0$

- • Change variables using $x = u-1$ so that the regular singular point is at $u = 0$

  $(2u^3 - 4u^2 + 2u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (3u^2 - 7u + 4)\left(\frac{d}{du}y(u)\right) + y(u) = 0$

1.115 problem 117

Internal problem ID [8253]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 117
Date solved : `Monday, October 21, 2024 at 05:04:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$6x^2\left(2x^2+1\right)y''+x\left(50x^2+1\right)y'+\left(30x^2+1\right)y=0$$

1.115.1 Solved as second order ode using Kovacic algorithm

Time used: 0.214 (sec)

Writing the ode as

$$\left(12x^4+6x^2\right)y''+\left(50x^3+x\right)y'+\left(30x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 12x^4+6x^2 \\ B &= 50x^3+x \\ C &= 30x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-35}{144x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -35$$
$$t = 144x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{35}{144x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 214: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{35}{144x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{35}{144x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{35}{144x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{12}$	$\frac{5}{12}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{12}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{5}{12} - \left(\frac{5}{12}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\ &= \frac{5}{12x} + (-)\,(0) \\ &= \frac{5}{12x} \\ &= \frac{5}{12x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{5}{12x}\right)(0) + \left(\left(-\frac{5}{12x^2}\right) + \left(\frac{5}{12x}\right)^2 - \left(-\frac{35}{144x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{5}{12x} dx} \\
&= x^{5/12}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{50x^3 + x}{12x^4 + 6x^2} \, dx} \\
&= z_1 e^{-\ln(2x^2+1) - \frac{\ln(x)}{12}} \\
&= z_1 \left(\frac{1}{(2x^2+1) \, x^{1/12}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{2x^2 + 1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{50x^3+x}{12x^4+6x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(2x^2+1)-\frac{\ln(x)}{6}}}{(y_1)^2}\,dx \\
&= y_1 \left(6x^{1/3}\mathrm{e}^{-2\ln(2x^2+1)-\frac{\ln(x)}{6}}\left(2x^2+1\right)^2\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/3}}{2x^2+1}\right) + c_2 \left(\frac{x^{1/3}}{2x^2+1}\left(6x^{1/3}\mathrm{e}^{-2\ln(2x^2+1)-\frac{\ln(x)}{6}}\left(2x^2+1\right)^2\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.115.2 Maple step by step solution

Let's solve

$6x^2(2x^2+1)\left(\frac{d}{dx}y'\right) + x(50x^2+1)\,y' + (30x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(30x^2+1)y}{6x^2(2x^2+1)} - \frac{(50x^2+1)y'}{6x(2x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(50x^2+1)y'}{6x(2x^2+1)} + \frac{(30x^2+1)y}{6x^2(2x^2+1)} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{50x^2+1}{6x(2x^2+1)}, P_3(x) = \frac{30x^2+1}{6x^2(2x^2+1)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{1}{6}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = \frac{1}{6}$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$6x^2(2x^2+1)\left(\frac{d}{dx}y'\right) + x(50x^2+1)\,y' + (30x^2+1)\,y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- Shift index using $k- >k + 2 - m$

  $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+3r)\,(-1+2r)\,x^r + a_1(2+3r)\,(1+2r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-1)\,(2k+2r-1) + 2a\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+3r)\,(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$r \in \left\{\frac{1}{2}, \frac{1}{3}\right\}$

- Each term must be 0

  $a_1(2+3r)(1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $(3k+3r-1)(2k+2r-1)(a_k+2a_{k-2}) = 0$
- Shift index using $k->k+2$

  $(3k+3r+5)(2k+2r+3)(a_{k+2}+2a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -2a_k$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -2a_k$
- Solution for $r = \frac{1}{2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -2a_k, a_1 = 0\right]$$
- Recursion relation for $r = \frac{1}{3}$

  $a_{k+2} = -2a_k$
- Solution for $r = \frac{1}{3}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -2a_k, a_1 = 0\right]$$
- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -2a_k, a_1 = 0, b_{k+2} = -2b_k, b_1 = 0\right]$$

1.116 problem 118

Internal problem ID [8254]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 118
Date solved : `Monday, October 21, 2024 at 05:04:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$28x^2(1-3x)\,y''-7x(5+9x)\,y'+7(2+9x)\,y=0$$

1.116.1 Solved as second order ode using Kovacic algorithm

Time used: 0.213 (sec)

Writing the ode as

$$\left(-84x^3+28x^2\right)y''+\left(-63x^2-35x\right)y'+(63x+14)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-84x^3+28x^2\\B&=-63x^2-35x\\C&=63x+14\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{33}{64x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 33 \\
t &= 64x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{33}{64x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 216: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{33}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{33}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{33}{64x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{33}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{8} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{8} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{33}{64x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{3}{8}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= -\frac{3}{8} - \left(-\frac{3}{8}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{8x} + (-)(0) \\
&= -\frac{3}{8x} \\
&= -\frac{3}{8x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered}(0) + 2\left(-\frac{3}{8x}\right)(0) + \left(\left(\frac{3}{8x^2}\right) + \left(-\frac{3}{8x}\right)^2 - \left(\frac{33}{64x^2}\right)\right) = 0 \\ 0 = 0\end{gathered}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int -\frac{3}{8x} dx} \\ &= \frac{1}{x^{3/8}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-63x^2 - 35x}{-84x^3 + 28x^2}\, dx} \\ &= z_1 e^{\frac{5\ln(x)}{8} - \ln(-1+3x)} \\ &= z_1 \left(\frac{x^{5/8}}{-1+3x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/4}}{-1+3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-63x^2-35x}{-84x^3+28x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{5\ln(x)}{4}-2\ln(-1+3x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{4\sqrt{x}\,\mathrm{e}^{\frac{5\ln(x)}{4}-2\ln(-1+3x)}(-1+3x)^2}{7}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/4}}{-1+3x}\right) + c_2\left(\frac{x^{1/4}}{-1+3x}\left(\frac{4\sqrt{x}\,\mathrm{e}^{\frac{5\ln(x)}{4}-2\ln(-1+3x)}(-1+3x)^2}{7}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.116.2 Maple step by step solution

Let's solve

$28x^2(1-3x)\left(\frac{d}{dx}y'\right) - 7x(5+9x)\,y' + 7(2+9x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(2+9x)y}{4x^2(-1+3x)} - \frac{(5+9x)y'}{4x(-1+3x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(5+9x)y'}{4x(-1+3x)} - \frac{(2+9x)y}{4x^2(-1+3x)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{5+9x}{4x(-1+3x)}, P_3(x) = -\frac{2+9x}{4x^2(-1+3x)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$$(x \cdot P_2(x))\bigg|_{x=0} = -\frac{5}{4}$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{1}{2}$$

- $x = 0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = 0$

- Multiply by denominators

$$4x^2(-1+3x)\left(\frac{d}{dx}y'\right) + x(5+9x)\,y' + (-9x-2)\,y = 0$$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(-1+4r)\,(-2+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(4k+4r-1)\,(k+r-2) + 3a_{k-1}(4k+4r-1)\,(k+r-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-(-1+4r)(-2+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{2, \frac{1}{4}\}$

- Each term in the series must be 0, giving the recursion relation

  $-4(k+r-2)\left(k+r-\frac{1}{4}\right)(a_k - 3a_{k-1}) = 0$

- Shift index using $k->k+1$

  $-4(k+r-1)\left(k+\frac{3}{4}+r\right)(a_{k+1} - 3a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = 3a_k$

- Recursion relation for $r = 2$

  $a_{k+1} = 3a_k$

- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = 3a_k\right]$

- Recursion relation for $r = \frac{1}{4}$

  $a_{k+1} = 3a_k$

- Solution for $r = \frac{1}{4}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+1} = 3a_k\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{4}}\right), a_{k+1} = 3a_k, b_{k+1} = 3b_k\right]$

1.117 problem 119

Internal problem ID [8255]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 119
Date solved : `Monday, October 21, 2024 at 05:04:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$8x^2\left(-x^2+2\right)y''+2x\left(-21x^2+10\right)y'-\left(35x^2+2\right)y=0$$

1.117.1 Solved as second order ode using Kovacic algorithm

Time used: 0.217 (sec)

Writing the ode as

$$\left(-8x^4+16x^2\right)y''+\left(-42x^3+20x\right)y'+\left(-35x^2-2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -8x^4+16x^2 \\ B &= -42x^3+20x \\ C &= -35x^2-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-7}{64x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -7$$
$$t = 64x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{7}{64x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 218: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{7}{64x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{7}{64x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{8}$	$\frac{1}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{8}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{8} - \left(\frac{1}{8}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{8x} + (-)(0) \\ &= \frac{1}{8x} \\ &= \frac{1}{8x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{8x}\right)(0)+\left(\left(-\frac{1}{8x^2}\right)+\left(\frac{1}{8x}\right)^2-\left(-\frac{7}{64x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int\omega\,dx}\\
&=\mathrm{e}^{\int\frac{1}{8x}dx}\\
&=x^{1/8}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int-\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int\frac{1}{2}\frac{-42x^3+20x}{-8x^4+16x^2}\,dx}\\
&=z_1e^{-\ln(x^2-2)-\frac{5\ln(x)}{8}}\\
&=z_1\left(\frac{1}{(x^2-2)\,x^{5/8}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{1}{(x^2-2)\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int-\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-42x^3+20x}{-8x^4+16x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2\ln(x^2-2)-\frac{5\ln(x)}{4}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{4x^2 \mathrm{e}^{-2\ln(x^2-2)-\frac{5\ln(x)}{4}} (x^2-2)^2}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{(x^2-2)\sqrt{x}}\right) + c_2 \left(\frac{1}{(x^2-2)\sqrt{x}} \left(\frac{4x^2 \mathrm{e}^{-2\ln(x^2-2)-\frac{5\ln(x)}{4}} (x^2-2)^2}{3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.117.2 Maple step by step solution

Let's solve

$8x^2(-x^2+2)\left(\frac{d}{dx}y'\right) + 2x(-21x^2+10)\, y' - (35x^2+2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(35x^2+2)y}{8x^2(x^2-2)} - \frac{(21x^2-10)y'}{4x(x^2-2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(21x^2-10)y'}{4x(x^2-2)} + \frac{(35x^2+2)y}{8x^2(x^2-2)} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{21x^2-10}{4x(x^2-2)}, P_3(x) = \frac{35x^2+2}{8x^2(x^2-2)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{5}{4}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{1}{8}$
- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $8x^2(x^2-2)\left(\frac{d}{dx}y'\right) + 2x(21x^2-10)\,y' + (35x^2+2)\,y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
- Shift index using $k- >k+2-m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0(1+2r)\,(-1+4r)\,x^r - 2a_1(3+2r)\,(3+4r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (-2a_k(2k+2r+1)\,(4k+4r-1)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2(1+2r)\,(-1+4r) = 0$
- Values of r that satisfy the indicial equation

$r \in \left\{-\frac{1}{2}, \frac{1}{4}\right\}$

- Each term must be 0

  $-2a_1(3+2r)(3+4r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $-(2k+2r+1)(4k+4r-1)(2a_k - a_{k-2}) = 0$

- Shift index using $k- > k+2$

  $-(2k+2r+5)(4k+4r+7)(2a_{k+2} - a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k}{2}$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = \frac{a_k}{2}$

- Solution for $r = -\frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = \frac{a_k}{2}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{4}$

  $a_{k+2} = \frac{a_k}{2}$

- Solution for $r = \frac{1}{4}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+2} = \frac{a_k}{2}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{4}}\right), a_{k+2} = \frac{a_k}{2}, a_1 = 0, b_{k+2} = \frac{b_k}{2}, b_1 = 0\right]$

1.118 problem 120

Internal problem ID [8256]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 120
Date solved : `Monday, October 21, 2024 at 05:04:29 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+3x+1\right)y''-4x\left(-3x^2-3x+1\right)y'+3\left(x^2-x+1\right)y=0$$

1.118.1 Solved as second order ode using Kovacic algorithm

Time used: 0.146 (sec)

Writing the ode as

$$\left(4x^4+12x^3+4x^2\right)y''+\left(12x^3+12x^2-4x\right)y'+\left(3x^2-3x+3\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+12x^3+4x^2 \\ B &= 12x^3+12x^2-4x \\ C &= 3x^2-3x+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 220: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - -\infty\\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{12x^3+12x^2-4x}{4x^4+12x^3+4x^2}\,dx}\\ &= z_1 e^{\frac{\ln(x)}{2}-\ln(x^2+3x+1)}\\ &= z_1\left(\frac{\sqrt{x}}{x^2+3x+1}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{x^2+3x+1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{12x^3+12x^2-4x}{4x^4+12x^3+4x^2}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{\ln(x)-2\ln(x^2+3x+1)}}{(y_1)^2}\,dx\\ &= y_1(x)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\sqrt{x}}{x^2+3x+1}\right) + c_2\left(\frac{\sqrt{x}}{x^2+3x+1}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.119 problem 121

Internal problem ID [8257]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 121
Date solved : `Monday, October 21, 2024 at 05:04:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2(1+x)^2 y'' - x\left(-11x^2 - 10x + 1\right) y' + \left(5x^2+1\right) y = 0$$

1.119.1 Solved as second order ode using Kovacic algorithm

Time used: 0.208 (sec)

Writing the ode as

$$3x^2(1+x)^2 y'' + \left(11x^3 + 10x^2 - x\right) y' + \left(5x^2+1\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2(1+x)^2 \\ B &= 11x^3 + 10x^2 - x \\ C &= 5x^2 + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -5 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{5}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 222: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{5}{36x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{5}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{6}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= \frac{1}{6} - \left(\frac{1}{6}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{6x} + (-)(0) \\
&= \frac{1}{6x} \\
&= \frac{1}{6x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{6x}\right)(0) + \left(\left(-\frac{1}{6x^2}\right) + \left(\frac{1}{6x}\right)^2 - \left(-\frac{5}{36x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{6x} dx} \\ &= x^{1/6} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{11x^3+10x^2-x}{3x^2(1+x)^2} \, dx} \\ &= z_1 e^{\frac{\ln(x)}{6} - 2\ln(1+x)} \\ &= z_1 \left(\frac{x^{1/6}}{(1+x)^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{(1+x)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{11x^3+10x^2-x}{3x^2(1+x)^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{\ln(x)}{3}-4\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{3x^{1/3}\mathrm{e}^{\frac{\ln(x)}{3}-4\ln(1+x)}(1+x)^4}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/3}}{(1+x)^2}\right) + c_2 \left(\frac{x^{1/3}}{(1+x)^2}\left(\frac{3x^{1/3}\mathrm{e}^{\frac{\ln(x)}{3}-4\ln(1+x)}(1+x)^4}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.119.2 Maple step by step solution

Let's solve

$3x^2(1+x)^2 \left(\frac{d}{dx}y'\right) - x(-11x^2-10x+1)\, y' + (5x^2+1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(5x^2+1)y}{3x^2(1+x)^2} - \frac{y'(11x-1)}{3x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

1.120 problem 122

Internal problem ID [8258]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 122
Date solved : `Monday, October 21, 2024 at 05:04:31 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+2x+3\right)y''-x\left(-15x^2-14x+3\right)y'+\left(7x^2+3\right)y=0$$

1.120.1 Solved as second order ode using Kovacic algorithm

Time used: 0.222 (sec)

Writing the ode as

$$\left(4x^4+8x^3+12x^2\right)y''+\left(15x^3+14x^2-3x\right)y'+\left(7x^2+3\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+8x^3+12x^2 \\ B &= 15x^3+14x^2-3x \\ C &= 7x^2+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-7}{64x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -7$$
$$t = 64x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{7}{64x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 224: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{7}{64x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{7}{64x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{8}$	$\frac{1}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{8}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{8} - \left(\frac{1}{8}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{8x} + (-)(0) \\ &= \frac{1}{8x} \\ &= \frac{1}{8x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered}(0) + 2\left(\frac{1}{8x}\right)(0) + \left(\left(-\frac{1}{8x^2}\right) + \left(\frac{1}{8x}\right)^2 - \left(-\frac{7}{64x^2}\right)\right) = 0 \\ 0 = 0\end{gathered}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \frac{1}{8x} dx} \\ &= x^{1/8}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{15x^3+14x^2-3x}{4x^4+8x^3+12x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{8} - \ln(x^2+2x+3)} \\ &= z_1 \left(\frac{x^{1/8}}{x^2+2x+3}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/4}}{x^2+2x+3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{15x^3+14x^2-3x}{4x^4+8x^3+12x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{\ln(x)}{4}-2\ln(x^2+2x+3)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{4\sqrt{x}\,\mathrm{e}^{\frac{\ln(x)}{4}-2\ln(x^2+2x+3)}\,(x^2+2x+3)^2}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/4}}{x^2+2x+3}\right) + c_2\left(\frac{x^{1/4}}{x^2+2x+3}\left(\frac{4\sqrt{x}\,\mathrm{e}^{\frac{\ln(x)}{4}-2\ln(x^2+2x+3)}\,(x^2+2x+3)^2}{3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.121 problem 123

Internal problem ID [8259]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 123
Date solved : `Monday, October 21, 2024 at 05:04:32 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2-2x+1)\,y''-x(3+x)\,y'+(4+x)\,y=0$$

1.121.1 Solved as second order ode using Kovacic algorithm

Time used: 0.370 (sec)

Writing the ode as

$$x^2(x-1)^2\,y''+\left(-x^2-3x\right)y'+(4+x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(x-1)^2 \\ B &= -x^2-3x \\ C &= 4+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{7x^2 + 10x - 1}{4x^2 (x-1)^4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 7x^2 + 10x - 1 \\
t &= 4x^2(x-1)^4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{7x^2 + 10x - 1}{4x^2 (x-1)^4}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 226: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2(x-1)^4$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{2(x-1)} + \frac{3}{2x} + \frac{4}{(x-1)^4} - \frac{2}{(x-1)^3} + \frac{7}{4(x-1)^2} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r=-\frac{3}{2(x-1)}+\frac{3}{2x}+\frac{4}{(x-1)^4}-\frac{2}{(x-1)^3}+\frac{7}{4(x-1)^2}-\frac{1}{4x^2}$$

There is pole in r at $x=1$ of order 4, hence $v=2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c=1$ gives

$$[\sqrt{r}]_c \approx \frac{2}{(x-1)^2}-\frac{1}{2(x-1)}+\frac{21}{32}-\frac{9x}{32}+\frac{53(x-1)^2}{256}-\frac{149(x-1)^3}{1024}+\dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v=2$ the above becomes

$$[\sqrt{r}]_c=\frac{2}{(x-1)^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-1)^2}$ is

$$a=2$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c=1$. This term becomes $\frac{1}{(x-1)^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be -2. Therefore

$$\begin{aligned}b&=(-2)-(0)\\&=-2\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_c&=\frac{2}{(x-1)^2}\\ \alpha_c^{+}&=\frac{1}{2}\left(\frac{b}{a}+v\right)&&=\frac{1}{2}\left(\frac{-2}{2}+2\right)&&=\frac{1}{2}\\ \alpha_c^{-}&=\frac{1}{2}\left(-\frac{b}{a}+v\right)&&=\frac{1}{2}\left(-\frac{-2}{2}+2\right)&&=\frac{3}{2}\end{aligned}$$

Since the order of r at ∞ is $4>2$ then

$$\begin{aligned}[\sqrt{r}]_\infty&=0\\ \alpha_\infty^{+}&=0\\ \alpha_\infty^{-}&=1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{7x^2 + 10x - 1}{4x^2 (x-1)^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
1	4	$\frac{2}{(x-1)^2}$	$\frac{1}{2}$	$\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2} + (-)(0) \\
&= \frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2} \\
&= \frac{2x^2 + x + 1}{2x (x-1)^2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{4}{(x-1)^3} - \frac{1}{2\,(x-1)^2}\right) + \left(\frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2}\right) dx} \\ &= \sqrt{x-1}\,\sqrt{x}\,\mathrm{e}^{-\frac{2}{x-1}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2-3x}{x^2(x-1)^2}\, dx} \\ &= z_1 e^{-\frac{2}{x-1} - \frac{3\ln(x-1)}{2} + \frac{3\ln(x)}{2}} \\ &= z_1 \left(\frac{x^{3/2}\mathrm{e}^{-\frac{2}{x-1}}}{(x-1)^{3/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{3/2}\mathrm{e}^{-\frac{4}{x-1}}\sqrt{x\,(x-1)}}{(x-1)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{-x^2-3x}{x^2(x-1)^2} dx}}{(y_1)^2} dx$$
$$= y_1 \int \frac{e^{-\frac{4}{x-1}-3\ln(x-1)+3\ln(x)}}{(y_1)^2} dx$$
$$= y_1 \left(\mathrm{e}^{-4} \operatorname{Ei}_1\left(-\frac{4}{x-1}-4\right)\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x^{3/2} \mathrm{e}^{-\frac{4}{x-1}} \sqrt{x(x-1)}}{(x-1)^{3/2}}\right) + c_2 \left(\frac{x^{3/2} \mathrm{e}^{-\frac{4}{x-1}} \sqrt{x(x-1)}}{(x-1)^{3/2}} \left(\mathrm{e}^{-4} \operatorname{Ei}_1\left(-\frac{4}{x-1}-4\right)\right)\right)$$

Will add steps showing solving for IC soon.

1.121.2 Maple step by step solution

Let's solve

$x^2(x^2-2x+1)\left(\frac{d}{dx}y'\right) - x(3+x)\,y' + (4+x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(4+x)y}{x^2(x^2-2x+1)} + \frac{(3+x)y'}{x(x^2-2x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{(3+x)y'}{x(x^2-2x+1)} + \frac{(4+x)y}{x^2(x^2-2x+1)} = 0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = -\frac{3+x}{x(x^2-2x+1)}, P_3(x) = \frac{4+x}{x^2(x^2-2x+1)}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = -3$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$(x^2 \cdot P_3(x))\bigg|_{x=0} = 4$

- ○ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$
- Multiply by denominators

  $x^2(x^2 - 2x + 1)\left(\frac{d}{dx}y'\right) - x(3 + x)\, y' + (4 + x)\, y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - ○ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ○ Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k + r)\, x^{k+r-1+m}$
  - ○ Shift index using $k- >k + 1 - m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$
  - ○ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

    $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k + r)\,(k + r - 1)\, x^{k+r-2+m}$
  - ○ Shift index using $k- >k + 2 - m$

    $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k + 2 - m + r)\,(k + 1 - m + r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2 + r)^2 x^r + \left(a_1(-1 + r)^2 - a_0(1 + 2r)\,(-1 + r)\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k + r - 2)^2 - a_{k-1}(2k -\right.\right.$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2 + r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 2$

- Each term must be 0

  $$a_1(-1+r)^2 - a_0(1+2r)(-1+r) = 0$$
- Solve for the dependent coefficient(s)

  $$a_1 = \frac{a_0(1+2r)}{-1+r}$$
- Each term in the series must be 0, giving the recursion relation

  $$((a_k + a_{k-2} - 2a_{k-1})k + (a_k + a_{k-2} - 2a_{k-1})r - 2a_k - 3a_{k-2} + a_{k-1})(k+r-2) = 0$$
- Shift index using $k->k+2$

  $$((a_{k+2} + a_k - 2a_{k+1})(k+2) + (a_{k+2} + a_k - 2a_{k+1})r - 2a_{k+2} - 3a_k + a_{k+1})(k+r) = 0$$
- Recursion relation that defines series solution to ODE

  $$a_{k+2} = -\frac{ka_k - 2ka_{k+1} + ra_k - 2ra_{k+1} - a_k - 3a_{k+1}}{k+r}$$
- Recursion relation for $r = 2$

  $$a_{k+2} = -\frac{ka_k - 2ka_{k+1} + a_k - 7a_{k+1}}{k+2}$$
- Solution for $r = 2$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{ka_k - 2ka_{k+1} + a_k - 7a_{k+1}}{k+2}, a_1 = 5a_0\right]$$

Solve

$$2x^2(2+x)\,y''+5x^2y'+(1+x)\,y=0$$

1.122.1 Solved as second order ode using Kovacic algorithm

Time used: 0.257 (sec)

Writing the ode as

$$\left(2x^3+4x^2\right)y''+5x^2y'+(1+x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x^3+4x^2\\B&=5x^2\\C&=1+x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3x^2 - 24x - 16}{16\left(x^2 + 2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3x^2 - 24x - 16 \\ t &= 16\left(x^2 + 2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3x^2 - 24x - 16}{16\left(x^2 + 2x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 228: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{5}{16\,(2+x)^2} - \frac{1}{8x} + \frac{1}{16+8x}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 - 24x - 16}{16\,(x^2+2x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{4} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-3x^2-24x-16}{16\left(x^2+2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-2	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right) \\
&= \frac{1}{4}-\left(\frac{1}{4}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{4\left(2+x\right)} + \frac{1}{2x} + (-)\left(0\right) \\
&= -\frac{1}{4\left(2+x\right)} + \frac{1}{2x} \\
&= \frac{x+4}{4x\left(2+x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{4\left(2+x\right)} + \frac{1}{2x}\right)(0) + \left(\left(\frac{1}{4\left(2+x\right)^2} - \frac{1}{2x^2}\right) + \left(-\frac{1}{4\left(2+x\right)} + \frac{1}{2x}\right)^2 - \left(\frac{-3x^2-24x-16}{16\left(x^2+2x\right)^2}\right)
$$

$$
0 =
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{4(2+x)} + \frac{1}{2x}\right) dx} \\
&= \frac{\sqrt{x}}{\left(2+x\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{5x^2}{2x^3+4x^2} \, dx} \\
&= z_1 e^{-\frac{5\ln(2+x)}{4}} \\
&= z_1 \left(\frac{1}{\left(2+x\right)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{(2+x)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5x^2}{2x^3+4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{5\ln(2+x)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(2\sqrt{2+x} - 2\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\sqrt{x}}{(2+x)^{3/2}}\right) + c_2\left(\frac{\sqrt{x}}{(2+x)^{3/2}}\left(2\sqrt{2+x} - 2\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.122.2 Maple step by step solution

Let's solve

$2x^2(2+x)\left(\frac{d}{dx}y'\right) + 5x^2y' + (1+x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(1+x)y}{2x^2(2+x)} - \frac{5y'}{2(2+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d}{dx}y' + \frac{5y'}{2(2+x)} + \frac{(1+x)y}{2x^2(2+x)} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions
    $\left[P_2(x) = \frac{5}{2(2+x)}, P_3(x) = \frac{1+x}{2x^2(2+x)}\right]$
  - $(2+x) \cdot P_2(x)$ is analytic at $x = -2$
    $\left((2+x) \cdot P_2(x)\right)\Big|_{x=-2} = \frac{5}{2}$
  - $(2+x)^2 \cdot P_3(x)$ is analytic at $x = -2$
    $\left((2+x)^2 \cdot P_3(x)\right)\Big|_{x=-2} = 0$
  - $x = -2$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = -2$

- Multiply by denominators
  $2x^2(2+x)\left(\frac{d}{dx}y'\right) + 5x^2y' + (1+x)\,y = 0$
- Change variables using $x = u - 2$ so that the regular singular point is at $u = 0$
  $(2u^3 - 8u^2 + 8u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (5u^2 - 20u + 20)\left(\frac{d}{du}y(u)\right) + (-1+u)\,y(u) = 0$
- Assume series solution for $y(u)$
  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$
    $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$
  - Shift index using $k- >k - m$
    $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$
    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k- >k + 1 - m$
    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

  $$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)(k+1-m+r) u^{k+r}$$

  Rewrite ODE with series expansions

  $$4a_0 r(3+2r) u^{-1+r} + (4a_1(1+r)(5+2r) - a_0(8r^2+12r+1)) u^r + \left(\sum_{k=1}^{\infty} (4a_{k+1}(k+r+1)(2k\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$4r(3+2r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, -\frac{3}{2}\right\}$$

- Each term must be 0

  $$4a_1(1+r)(5+2r) - a_0(8r^2+12r+1) = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$2(-4a_k + a_{k-1} + 4a_{k+1}) k^2 + (4(-4a_k + a_{k-1} + 4a_{k+1}) r - 12a_k - a_{k-1} + 28a_{k+1}) k + 2(-4a_k +$$

- Shift index using $k->k+1$

  $$2(-4a_{k+1} + a_k + 4a_{k+2}) (k+1)^2 + (4(-4a_{k+1} + a_k + 4a_{k+2}) r - 12a_{k+1} - a_k + 28a_{k+2}) (k+1) -$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + 4kr a_k - 16kr a_{k+1} + 2r^2 a_k - 8r^2 a_{k+1} + 3k a_k - 28k a_{k+1} + 3r a_k - 28r a_{k+1} + a_k - 21 a_{k+1}}{4(2k^2+4kr+2r^2+11k+11r+14)}$$

- Recursion relation for $r = 0$

  $$a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + 3k a_k - 28k a_{k+1} + a_k - 21 a_{k+1}}{4(2k^2+11k+14)}$$

- Solution for $r = 0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + 3k a_k - 28k a_{k+1} + a_k - 21 a_{k+1}}{4(2k^2+11k+14)}, 20a_1 - a_0 = 0\right]$$

- Revert the change of variables $u = 2 + x$

  $$\left[y = \sum_{k=0}^{\infty} a_k (2+x)^k, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + 3k a_k - 28k a_{k+1} + a_k - 21 a_{k+1}}{4(2k^2+11k+14)}, 20a_1 - a_0 = 0\right]$$

- Recursion relation for $r = -\frac{3}{2}$

  $$a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} - 3k a_k - 4k a_{k+1} + a_k + 3 a_{k+1}}{4(2k^2+5k+2)}$$

- Solution for $r = -\frac{3}{2}$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{3}{2}}, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} - 3k a_k - 4k a_{k+1} + a_k + 3 a_{k+1}}{4(2k^2+5k+2)}, -4a_1 - a_0 = 0\right]$$

- Revert the change of variables $u = 2 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (2+x)^{k-\frac{3}{2}}, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} - 3k a_k - 4k a_{k+1} + a_k + 3a_{k+1}}{4(2k^2+5k+2)}, -4a_1 - a_0 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (2+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (2+x)^{k-\frac{3}{2}}\right), a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + 3k a_k - 28k a_{k+1} + a_k - 21 a_{k+1}}{4(2k^2+11k+14)}, 20a\right.$$

1.123 problem 125

Internal problem ID [8261]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 125
Date solved : `Monday, October 21, 2024 at 05:04:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(-x^2+2\right) y''-2x\left(2x^2+1\right) y'+\left(-2x^2+2\right) y=0$$

1.123.1 Solved as second order ode using Kovacic algorithm

Time used: 0.442 (sec)

Writing the ode as

$$\left(-x^4+2x^2\right) y''+\left(-4x^3-2x\right) y'+\left(-2x^2+2\right) y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^4+2x^2 \\ B &= -4x^3-2x \\ C &= -2x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{3x^2 - 1}{(x^3 - 2x)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 3x^2 - 1 \\
t &= (x^3 - 2x)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{3x^2 - 1}{(x^3 - 2x)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 230: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^3 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \sqrt{2}$ of order 2. There is a pole at $x = -\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{5}{16\left(x - \sqrt{2}\right)^2} + \frac{5}{16\left(x + \sqrt{2}\right)^2} - \frac{3\sqrt{2}}{32\left(x - \sqrt{2}\right)} + \frac{3\sqrt{2}}{32\left(x + \sqrt{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x = -\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^2 - 1}{\left(x^3 - 2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\sqrt{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-\sqrt{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = 0$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{-} + \alpha_{c_3}^{-}\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x - c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{1}{4\left(x - \sqrt{2}\right)} - \frac{1}{4\left(x + \sqrt{2}\right)} + (0) \\
&= \frac{1}{2x} - \frac{1}{4\left(x - \sqrt{2}\right)} - \frac{1}{4\left(x + \sqrt{2}\right)} \\
&= -\frac{1}{x^3 - 2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{1}{4\left(x - \sqrt{2}\right)} - \frac{1}{4\left(x + \sqrt{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{4\left(x - \sqrt{2}\right)^2} + \frac{1}{4\left(x + \sqrt{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{}{4(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{4\left(x - \sqrt{2}\right)} - \frac{1}{4\left(x + \sqrt{2}\right)} \right) dx} \\
&= \frac{\sqrt{x}}{\left(x - \sqrt{2}\right)^{1/4} \left(x + \sqrt{2}\right)^{1/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x^3-2x}{-x^4+2x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}-\frac{5\ln\left(x^2-2\right)}{4}} \\
&= z_1 \left(\frac{\sqrt{x}}{\left(x^2-2\right)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x}{\left(x^2-2\right)^{3/2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^3-2x}{-x^4+2x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)-\frac{5\ln\left(x^2-2\right)}{2}}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\sqrt{x^2-2}+\sqrt{2}\,\arctan\left(\frac{\sqrt{2}}{\sqrt{x^2-2}}\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x}{\left(x^2-2\right)^{3/2}}\right) + c_2 \left(\frac{x}{\left(x^2-2\right)^{3/2}}\left(\sqrt{x^2-2}+\sqrt{2}\,\arctan\left(\frac{\sqrt{2}}{\sqrt{x^2-2}}\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.123.2 Maple step by step solution

Let's solve

$x^2(-x^2+2)\left(\frac{d}{dx}y'\right)-2x(2x^2+1)\,y'+(-2x^2+2)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{2(x^2-1)y}{x^2(x^2-2)}-\frac{2(2x^2+1)y'}{x(x^2-2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{2(2x^2+1)y'}{x(x^2-2)}+\frac{2(x^2-1)y}{x^2(x^2-2)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{2(2x^2+1)}{x(x^2-2)},P_3(x)=\frac{2(x^2-1)}{x^2(x^2-2)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$\left.(x\cdot P_2(x))\right|_{x=0}=-1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left.(x^2\cdot P_3(x))\right|_{x=0}=1$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$x^2(x^2-2)\left(\frac{d}{dx}y'\right)+2x(2x^2+1)\,y'+(2x^2-2)\,y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

$x^m\cdot y=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

- ◦ Shift index using $k->k-m$

$x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0(-1+r)^2\, x^r - 2a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(-2a_k(k+r-1)^2 + a_{k-2}(k+r)\,(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2(-1+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 1$$

- Each term must be 0

$$-2a_1 r^2 = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$-2a_k(k+r-1)^2 + a_{k-2}(k+r)\,(k+r-1) = 0$$

- Shift index using $k->k+2$

$$-2a_{k+2}(k+r+1)^2 + a_k(k+r+2)\,(k+r+1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{a_k(k+r+2)}{2(k+r+1)}$$

- Recursion relation for $r = 1$

$$a_{k+2} = \frac{a_k(k+3)}{2(k+2)}$$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = \frac{a_k(k+3)}{2(k+2)}, a_1 = 0\right]$$

1.124 problem 126

Internal problem ID [8262]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 126
Date solved : `Monday, October 21, 2024 at 05:04:36 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x(5-x)\,y' + (9-4x)\,y = 0$$

1.124.1 Solved as second order ode using Kovacic algorithm

Time used: 0.545 (sec)

Writing the ode as

$$x^2y'' + \left(x^2-5x\right)y' + (9-4x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2-5x \\ C &= 9-4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{x^2 + 6x - 1}{4x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= x^2 + 6x - 1 \\
t &= 4x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{x^2 + 6x - 1}{4x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 232: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{3}{2x} - \frac{5}{2x^2} + \frac{15}{2x^3} - \frac{115}{4x^4} + \frac{495}{4x^5} - \frac{2285}{4x^6} + \frac{11055}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 6x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{6x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{6x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 6. Dividing this by leading coefficient in t which is 4 gives $\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{3}{2}\right) - (0) \\ &= \frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{3}{2}}{\frac{1}{2}} - 0\right) &= \frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{3}{2}}{\frac{1}{2}} - 0\right) &= -\frac{3}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 6x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{3}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\ &= \frac{3}{2} - \left(\frac{1}{2}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2x} + \frac{1}{2} \\
&= \frac{1+x}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{1}{2}\right)(1) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} + \frac{1}{2}\right)^2 - \left(\frac{x^2+6x-1}{4x^2}\right) \right) = 0$$

$$\frac{1-a_0}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = 1 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (1+x)\, e^{\int \left(\frac{1}{2x} + \frac{1}{2}\right) dx} \\
&= (1+x)\, e^{\frac{x}{2} + \frac{\ln(x)}{2}} \\
&= (1+x)\sqrt{x}\, e^{\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2-5x}{x^2}\,dx} \\
&= z_1 e^{-\frac{x}{2}+\frac{5\ln(x)}{2}} \\
&= z_1\left(x^{5/2}\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^3(1+x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2-5x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x+5\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\operatorname{Ei}_1(x) - \frac{\mathrm{e}^{-x}}{-1-x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^3(1+x)\right) + c_2\left(x^3(1+x)\left(-\operatorname{Ei}_1(x) - \frac{\mathrm{e}^{-x}}{-1-x}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.124.2 Maple step by step solution

Let's solve

$x^2\left(\frac{d}{dx}y'\right) - x(5-x)\,y' + (9-4x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(-9+4x)y}{x^2} - \frac{(-5+x)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(-5+x)y'}{x} - \frac{(-9+4x)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{-5+x}{x}, P_3(x) = -\frac{-9+4x}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = -5$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 9$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d}{dx}y'\right) + x(-5+x)\,y' + (9-4x)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

$$x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-3+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-3)^2 + a_{k-1}(k-5+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(-3+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 3$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r-3)^2 + a_{k-1}(k-5+r) = 0$$

- Shift index using $k- >k+1$

$$a_{k+1}(k-2+r)^2 + a_k(k+r-4) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k(k+r-4)}{(k-2+r)^2}$$

- Recursion relation for $r=3$; series terminates at $k=1$

$$a_{k+1} = -\frac{a_k(k-1)}{(k+1)^2}$$

- Apply recursion relation for $k=0$

$$a_1 = a_0$$

- Terminating series solution of the ODE for $r=3$. Use reduction of order to find the second li

$$y = a_0 \cdot (1+x)$$

1.125 problem 127

Internal problem ID [8263]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 127
Date solved : `Monday, October 21, 2024 at 05:04:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+x+1\right)y''+12x^2(1+x)\,y'+\left(3x^2+3x+1\right)y=0$$

1.125.1 Solved as second order ode using Kovacic algorithm

Time used: 0.865 (sec)

Writing the ode as

$$\left(4x^4+4x^3+4x^2\right)y''+\left(12x^3+12x^2\right)y'+\left(3x^2+3x+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= 4x^4+4x^3+4x^2\\ B &= 12x^3+12x^2\\ C &= 3x^2+3x+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2x^2 - 4x - 1}{4\left(x^3 + x^2 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2x^2 - 4x - 1$$
$$t = 4\left(x^3 + x^2 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2x^2 - 4x - 1}{4\left(x^3 + x^2 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 234: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{-\frac{3}{8} - \frac{i\sqrt{3}}{8}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{3}{8} + \frac{i\sqrt{3}}{8}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{\frac{1}{4} - \frac{5i\sqrt{3}}{12}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{4} + \frac{5i\sqrt{3}}{12}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} - \frac{1}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{8} - \frac{i\sqrt{3}}{8}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{\sqrt{-2 - 2i\sqrt{3}}}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{\sqrt{-2 - 2i\sqrt{3}}}{4} \end{aligned}$$

For the pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{8} + \frac{i\sqrt{3}}{8}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{-2+2i\sqrt{3}}}{4} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{2x^2 - 4x - 1}{4\left(x^3 + x^2 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2} + \frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2} + \frac{\sqrt{-2-2i\sqrt{3}}}{4}$	$\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}$
$-\frac{1}{2} - \frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2} + \frac{\sqrt{-2+2i\sqrt{3}}}{4}$	$\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{-} + \alpha_{c_3}^{-}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} + (-)\,(0) \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} \\
&= \frac{2x^2+1}{2x\,(x^2+x+1)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} \right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} - \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} \right) -$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} \right) dx} \\
&= \sqrt{x}\,(x^2+x+1)^{1/4}\,\sqrt{2}\, e^{-\frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{12x^3+12x^2}{4x^4+4x^3+4x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln\left(x^2+x+1\right)}{4}-\frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{2}}}{\left(x^2+x+1\right)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^{-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\sqrt{x}\,\sqrt{2}}{\sqrt{x^2+x+1}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{12x^3+12x^2}{4x^4+4x^3+4x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln\left(x^2+x+1\right)}{2}-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{3\ln\left(x^2+x+1\right)}{2}-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\left(x^2+x+1\right)\mathrm{e}^{2\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}}{2x}\,dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\sqrt{x}\,\sqrt{2}}{\sqrt{x^2+x+1}}\right) \\
&\quad + c_2 \left(\frac{e^{-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\sqrt{x}\,\sqrt{2}}{\sqrt{x^2+x+1}}\left(\int \frac{e^{-\frac{3\ln\left(x^2+x+1\right)}{2}-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\left(x^2+x+1\right)e^{2\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}}{2x}dx
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.125.2 Maple step by step solution

Let's solve

$4x^2(x^2+x+1)\left(\frac{d}{dx}y'\right)+12x^2(1+x)\,y'+(3x^2+3x+1)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(3x^2+3x+1)y}{4x^2(x^2+x+1)}-\frac{3(1+x)y'}{x^2+x+1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{3(1+x)y'}{x^2+x+1}+\frac{(3x^2+3x+1)y}{4x^2(x^2+x+1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{3(1+x)}{x^2+x+1}, P_3(x)=\frac{3x^2+3x+1}{4x^2(x^2+x+1)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=0$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=\frac{1}{4}$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $4x^2(x^2+x+1)\left(\frac{d}{dx}y'\right)+12x^2(1+x)\,y'+(3x^2+3x+1)\,y=0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot y'$ to series expansion for $m = 2..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k + r)\, x^{k+r-1+m}$

  - Shift index using $k- >k + 1 - m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx} y'\right)$ to series expansion for $m = 2..4$

    $x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k(k + r)\,(k + r - 1)\, x^{k+r-2+m}$

  - Shift index using $k- >k + 2 - m$

    $x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k + 2 - m + r)\,(k + 1 - m + r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1 + 2r)^2 x^r + \left(a_1(1 + 2r)^2 + a_0(3 + 2r)\,(1 + 2r)\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k + 2r - 1)^2 + a_{k-1}(2k\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1 + 2r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{2}$

- Each term must be 0

  $a_1(1 + 2r)^2 + a_0(3 + 2r)\,(1 + 2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = -\frac{(3+2r)a_0}{1+2r}$

- Each term in the series must be 0, giving the recursion relation

  $4\left(k + r - \frac{1}{2}\right)\left((a_k + a_{k-2} + a_{k-1})\, k + (a_k + a_{k-2} + a_{k-1})\, r - \frac{a_k}{2} - \frac{3a_{k-2}}{2} + \frac{a_{k-1}}{2}\right) = 0$

- Shift index using $k->k+2$

$$4\left(k+\frac{3}{2}+r\right)\left(\left(a_{k+2}+a_k+a_{k+1}\right)(k+2)+\left(a_{k+2}+a_k+a_{k+1}\right)r-\frac{a_{k+2}}{2}-\frac{3a_k}{2}+\frac{a_{k+1}}{2}\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{2ka_k+2ka_{k+1}+2ra_k+2ra_{k+1}+a_k+5a_{k+1}}{2k+2r+3}$$

- Recursion relation for $r=\frac{1}{2}$

$$a_{k+2}=-\frac{2ka_k+2ka_{k+1}+2a_k+6a_{k+1}}{2k+4}$$

- Solution for $r=\frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}, a_{k+2}=-\frac{2ka_k+2ka_{k+1}+2a_k+6a_{k+1}}{2k+4}, a_1=-2a_0\right]$$

Solve

$$x^2(x^2+x+1)\,y''-x(-2x^2-4x+1)\,y'+y=0$$

1.126.1 Solved as second order ode using Kovacic algorithm

Time used: 0.914 (sec)

Writing the ode as

$$x^2(x^2+x+1)\,y''+(2x^3+4x^2-x)\,y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2(x^2+x+1)\\ B&=2x^3+4x^2-x\\ C&=1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{10x^2 - 8x - 1}{4\left(x^3 + x^2 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 10x^2 - 8x - 1 \\
t &= 4\left(x^3 + x^2 + x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{10x^2 - 8x - 1}{4\left(x^3 + x^2 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 236: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{2x} - \frac{1}{4x^2} + \frac{-\frac{29}{24} - \frac{7i\sqrt{3}}{24}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{29}{24} + \frac{7i\sqrt{3}}{24}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{\frac{3}{4} - \frac{41i\sqrt{3}}{36}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{3}{4} + \frac{41i\sqrt{3}}{36}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{29}{24} - \frac{7i\sqrt{3}}{24}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{-138 - 42i\sqrt{3}}}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{-138 - 42i\sqrt{3}}}{12} \end{aligned}$$

For the pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{29}{24} + \frac{7i\sqrt{3}}{24}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{-138+42i\sqrt{3}}}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{10x^2 - 8x - 1}{4\left(x^3 + x^2 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2} + \frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2} + \frac{\sqrt{-138-42i\sqrt{3}}}{12}$	$\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}$
$-\frac{1}{2} - \frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2} + \frac{\sqrt{-138+42i\sqrt{3}}}{12}$	$\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x - c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} + (-)(0) \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} \\
&= \frac{2x^2 - 2x + 1}{2x(x^2 + x + 1)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} \right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} - \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right.}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} \right) dx} \\
&= (x^2 + x + 1)^{1/4} \sqrt{2}\, \sqrt{x}\, e^{-\frac{7\sqrt{3} \arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3+4x^2-x}{x^2(x^2+x+1)}\,dx} \\
&= z_1 e^{-\frac{3\ln(x^2+x+1)}{4}-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}+\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{\sqrt{x}\,\mathrm{e}^{-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}}{(x^2+x+1)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x\,\mathrm{e}^{-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{\sqrt{x^2+x+1}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+4x^2-x}{x^2(x^2+x+1)}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln(x^2+x+1)}{2}-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{3\ln(x^2+x+1)}{2}-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}+\ln(x)}(x^2+x+1)\,\mathrm{e}^{\frac{14\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{2x^2}dx\right)
\end{aligned}
$$

Therefore the solution is

$$y = c_1y_1 + c_2y_2$$

$$= c_1\left(\frac{x\,\mathrm{e}^{-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{\sqrt{x^2+x+1}}\right)$$

$$+c_2\left(\frac{x\,\mathrm{e}^{-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{\sqrt{x^2+x+1}}\left(\int \frac{\mathrm{e}^{-\frac{3\ln\left(x^2+x+1\right)}{2}-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}+\ln(x)}(x^2+x+1)\,\mathrm{e}^{\frac{14\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{2x^2}\right.\right.$$

Will add steps showing solving for IC soon.

1.126.2 Maple step by step solution

Let's solve

$x^2(x^2+x+1)\left(\frac{d}{dx}y'\right) - x(-2x^2-4x+1)\,y' + y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{x^2(x^2+x+1)} - \frac{(2x^2+4x-1)\,y'}{x(x^2+x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(2x^2+4x-1)\,y'}{x(x^2+x+1)} + \frac{y}{x^2(x^2+x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{2x^2+4x-1}{x(x^2+x+1)}, P_3(x) = \frac{1}{x^2(x^2+x+1)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 1$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(x^2+x+1)\left(\frac{d}{dx}y'\right) + x(2x^2+4x-1)\,y' + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  ○ Shift index using $k->k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  ○ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

  ○ Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)^2 x^r + \left(a_1 r^2 + a_0 r(3+r)\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-1}(k+r-1)\,(k+2+r)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term must be 0

  $a_1 r^2 + a_0 r(3+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = -\frac{(3+r)a_0}{r}$

- Each term in the series must be 0, giving the recursion relation

  $\left((a_k + a_{k-2} + a_{k-1})\, k + (a_k + a_{k-2} + a_{k-1})\, r - a_k - 2a_{k-2} + 2a_{k-1}\right)(k+r-1) = 0$

- Shift index using $k->k+2$

  $\left((a_{k+2} + a_k + a_{k+1})\,(k+2) + (a_{k+2} + a_k + a_{k+1})\, r - a_{k+2} - 2a_k + 2a_{k+1}\right)(k+r+1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k a_k + k a_{k+1} + r a_k + r a_{k+1} + 4 a_{k+1}}{k+r+1}$

- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{k a_k + k a_{k+1} + a_k + 5 a_{k+1}}{k+2}$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{k a_k + k a_{k+1} + a_k + 5 a_{k+1}}{k+2}, a_1 = -4 a_0\right]$$

Solve

$$9x^2y'' + 3x\left(-2x^2+3x+5\right)y' + \left(-14x^2+12x+1\right)y = 0$$

1.127.1 Solved as second order ode using Kovacic algorithm

Time used: 0.576 (sec)

Writing the ode as

$$9x^2y'' + \left(-6x^3+9x^2+15x\right)y' + \left(-14x^2+12x+1\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= -6x^3+9x^2+15x \\ C &= -14x^2+12x+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4x^4 - 12x^3 + 33x^2 - 18x - 9$$
$$t = 36x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 238: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 4 \\
&= -2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{9} - \frac{x}{3} + \frac{11}{12} - \frac{1}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i \qquad (8)
\end{aligned}
$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{3} - \frac{1}{2} + \frac{1}{x} + \frac{3}{4x^2} - \frac{3}{4x^3} - \frac{27}{8x^4} - \frac{117}{32x^5} + \frac{405}{64x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{3}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= -\frac{1}{2} + \frac{x}{3}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4} - \frac{1}{3}x + \frac{1}{9}x^2$$

This shows that the coefficient of 1 in the above is $\frac{1}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{9}x^2 - \frac{1}{3}x + \frac{11}{12}\right) + \left(\frac{-18x - 9}{36x^2}\right) \\ &= \frac{x^2}{9} - \frac{x}{3} + \frac{11}{12} + \frac{-18x - 9}{36x^2}\end{aligned}$$

We see that the coefficient of the term x in the quotient is $\frac{11}{12}$. Now b can be found.

$$\begin{aligned}b &= \left(\frac{11}{12}\right) - \left(\frac{1}{4}\right) \\ &= \frac{2}{3}\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= -\frac{1}{2} + \frac{x}{3} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= -\frac{3}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$-\frac{1}{2} + \frac{x}{3}$	$\frac{1}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + \left(-\frac{1}{2} + \frac{x}{3}\right) \\
&= \frac{1}{2x} - \frac{1}{2} + \frac{x}{3} \\
&= \frac{1}{2x} - \frac{1}{2} + \frac{x}{3}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} - \frac{1}{2} + \frac{x}{3}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{3}\right) + \left(\frac{1}{2x} - \frac{1}{2} + \frac{x}{3}\right)^2 - \left(\frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2}\right)\right) = 0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{2} + \frac{x}{3}\right) dx} \\
&= \sqrt{x}\, \mathrm{e}^{\frac{x(x-3)}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-6x^3 + 9x^2 + 15x}{9x^2} \, dx} \\
&= z_1 e^{\frac{x^2}{6} - \frac{x}{2} - \frac{5 \ln(x)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x(x-3)}{6}}}{x^{5/6}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{e^{\frac{x(x-3)}{3}}}{x^{1/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6x^3+9x^2+15x}{9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{x^2}{3}-x-\frac{5\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int e^{\frac{x^2}{3}-x-\frac{5\ln(x)}{3}} x^{2/3} e^{-\frac{2x(x-3)}{3}}\,dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{\frac{x(x-3)}{3}}}{x^{1/3}}\right) + c_2 \left(\frac{e^{\frac{x(x-3)}{3}}}{x^{1/3}} \left(\int e^{\frac{x^2}{3}-x-\frac{5\ln(x)}{3}} x^{2/3} e^{-\frac{2x(x-3)}{3}}\,dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.127.2 Maple step by step solution

Let's solve

$9x^2\left(\frac{d}{dx}y'\right) + 3x(-2x^2+3x+5)\,y' + (-14x^2+12x+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(14x^2-12x-1)y}{9x^2} + \frac{(2x^2-3x-5)y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{(2x^2-3x-5)y'}{3x} - \frac{(14x^2-12x-1)y}{9x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = -\frac{2x^2-3x-5}{3x}, P_3(x) = -\frac{14x^2-12x-1}{9x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Bigg|_{x=0} = \frac{5}{3}$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Bigg|_{x=0} = \frac{1}{9}$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- • Multiply by denominators

  $9x^2\left(\frac{d}{dx}y'\right) - 3x(2x^2 - 3x - 5)\, y' + (-14x^2 + 12x + 1)\, y = 0$

- • Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k + r)\, x^{k+r-1+m}$

- ○ Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$

- ○ Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k + r)\,(k + r - 1)\, x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(1+3r)^2 x^r + \left(a_1(4+3r)^2 + 3a_0(4+3r)\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r+1)^2 + 3a_{k-1}(3k+3r+1\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+3r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = -\frac{1}{3}$
- Each term must be 0
  $a_1(4+3r)^2 + 3a_0(4+3r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = -\frac{3a_0}{4+3r}$
- Each term in the series must be 0, giving the recursion relation
  $a_k(3k+3r+1)^2 + (3k+3r+1)(-2a_{k-2} + 3a_{k-1}) = 0$
- Shift index using $k- >k+2$
  $a_{k+2}(3k+3r+7)^2 + (3k+3r+7)(-2a_k + 3a_{k+1}) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{2a_k - 3a_{k+1}}{3k+3r+7}$
- Recursion relation for $r = -\frac{1}{3}$
  $a_{k+2} = \frac{2a_k - 3a_{k+1}}{3k+6}$
- Solution for $r = -\frac{1}{3}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+2} = \frac{2a_k - 3a_{k+1}}{3k+6}, a_1 = -a_0\right]$

1.128 problem 130

Internal problem ID [8266]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 130
Date solved : `Monday, October 21, 2024 at 05:04:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+2x)\,y''+x\left(3x^2+14x+5\right)y'+\left(12x^2+18x+4\right)y=0$$

1.128.1 Solved as second order ode using Kovacic algorithm

Time used: 0.645 (sec)

Writing the ode as

$$\left(2x^3+x^2\right)y''+\left(3x^3+14x^2+5x\right)y'+\left(12x^2+18x+4\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+x^2 \\ B &= 3x^3+14x^2+5x \\ C &= 12x^2+18x+4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{9x^4 - 12x^3 - 16x^2 - 4x - 1}{4\left(2x^2 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 9x^4 - 12x^3 - 16x^2 - 4x - 1 \\
t &= 4\left(2x^2 + x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{9x^4 - 12x^3 - 16x^2 - 4x - 1}{4\left(2x^2 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 240: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 4 \\
&= 0
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{16} - \frac{1}{4x^2} - \frac{15}{64\left(x + \frac{1}{2}\right)^2} - \frac{21}{16\left(x + \frac{1}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{3}{8}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i \qquad (8)
\end{aligned}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{3}{4} - \frac{7}{8x} - \frac{19}{48x^2} - \frac{151}{288x^3} - \frac{139}{192x^4} - \frac{11383}{10368x^5} - \frac{38729}{20736x^6} - \frac{1212655}{373248x^7} + \dots \qquad (9)
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{3}{4}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{3}{4} \qquad (10)
\end{aligned}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{9}{16}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading

coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{9x^4 - 12x^3 - 16x^2 - 4x - 1}{16x^4 + 16x^3 + 4x^2} \\
&= Q + \frac{R}{16x^4 + 16x^3 + 4x^2} \\
&= \left(\frac{9}{16}\right) + \left(\frac{-21x^3 - \frac{73}{4}x^2 - 4x - 1}{16x^4 + 16x^3 + 4x^2}\right) \\
&= \frac{9}{16} + \frac{-21x^3 - \frac{73}{4}x^2 - 4x - 1}{16x^4 + 16x^3 + 4x^2}
\end{aligned}
$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -21. Dividing this by leading coefficient in t which is 16 gives $-\frac{21}{16}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{21}{16}\right) - (0) \\
&= -\frac{21}{16}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{3}{4} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{21}{16}}{\frac{3}{4}} - 0\right) &= -\frac{7}{8} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{21}{16}}{\frac{3}{4}} - 0\right) &= \frac{7}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{9x^4 - 12x^3 - 16x^2 - 4x - 1}{4\left(2x^2 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2}$	2	0	$\frac{5}{8}$	$\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{3}{4}$	$-\frac{7}{8}$	$\frac{7}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{7}{8}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{-}\right) \\ &= \frac{7}{8} - \left(\frac{7}{8}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + \frac{3}{8\left(x+\frac{1}{2}\right)} + (-)\left(\frac{3}{4}\right) \\ &= \frac{1}{2x} + \frac{3}{8\left(x+\frac{1}{2}\right)} - \frac{3}{4} \\ &= \frac{-3x^2+2x+1}{4x^2+2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{3}{8\left(x+\frac{1}{2}\right)} - \frac{3}{4}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{3}{8\left(x+\frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} + \frac{3}{8\left(x+\frac{1}{2}\right)} - \frac{3}{4}\right)^2 - \left(\frac{9x^4 - 12x}{4}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{3}{8\left(x+\frac{1}{2}\right)} - \frac{3}{4}\right) dx} \\
&= (1+2x)^{3/8} \sqrt{x}\, \mathrm{e}^{-\frac{3x}{4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{3x^3+14x^2+5x}{2x^3+x^2} \, dx} \\
&= z_1 e^{-\frac{3x}{4} - \frac{5\ln(1+2x)}{8} - \frac{5\ln(x)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{3x}{4}}}{(1+2x)^{5/8} x^{5/2}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-\frac{3x}{2}}}{(1+2x)^{1/4} x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3+14x^2+5x}{2x^3+x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{3x}{2} - \frac{5\ln(1+2x)}{4} - 5\ln(x)}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \mathrm{e}^{-\frac{3x}{2} - \frac{5\ln(1+2x)}{4} - 5\ln(x)} \sqrt{1+2x}\, x^4 \mathrm{e}^{3x} dx \right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{-\frac{3x}{2}}}{(1+2x)^{1/4}\, x^2}\right) + c_2 \left(\frac{e^{-\frac{3x}{2}}}{(1+2x)^{1/4}\, x^2} \left(\int e^{-\frac{3x}{2}-\frac{5\ln(1+2x)}{4}-5\ln(x)} \sqrt{1+2x}\, x^4 e^{3x} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.128.2 Maple step by step solution

Let's solve

$x^2(1+2x)\left(\frac{d}{dx}y'\right)+x(3x^2+14x+5)\,y'+(12x^2+18x+4)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{2(6x^2+9x+2)y}{x^2(1+2x)} - \frac{(3x^2+14x+5)y'}{x(1+2x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(3x^2+14x+5)y'}{x(1+2x)} + \frac{2(6x^2+9x+2)y}{x^2(1+2x)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{3x^2+14x+5}{x(1+2x)}, P_3(x) = \frac{2(6x^2+9x+2)}{x^2(1+2x)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x=0$

    $(x \cdot P_2(x))\Big|_{x=0} = 5$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x=0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = 4$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(1+2x)\left(\frac{d}{dx}y'\right)+x(3x^2+14x+5)\,y'+(12x^2+18x+4)\,y=0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
- Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k- >k + 2 - m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)^2 x^r + \left(a_1(3+r)^2 + 2a_0(3+r)^2\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r+2)^2 + 2a_{k-1}(k+r+2)^2 + 3a\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = -2$
- Each term must be 0

  $a_1(3+r)^2 + 2a_0(3+r)^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = -2a_0$
- Each term in the series must be 0, giving the recursion relation

  $((2k+2r+4)\, a_{k-1} + a_k(k+r+2) + 3a_{k-2})\,(k+r+2) = 0$
- Shift index using $k- >k + 2$

  $((2k+8+2r)\, a_{k+1} + a_{k+2}(k+r+4) + 3a_k)\,(k+r+4) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2ka_{k+1}+2ra_{k+1}+3a_k+8a_{k+1}}{k+r+4}$
- Recursion relation for $r = -2$

$$a_{k+2} = -\frac{2ka_{k+1} + 3a_k + 4a_{k+1}}{k+2}$$

- Solution for $r = -2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{2ka_{k+1} + 3a_k + 4a_{k+1}}{k+2}, a_1 = -2a_0\right]$$

1.129 problem 131

Internal problem ID [8267]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 131
Date solved : `Monday, October 21, 2024 at 05:04:51 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$16x^2y'' + 4x\left(2x^2 + x + 6\right) y' + \left(18x^2 + 5x + 1\right) y = 0$$

1.129.1 Solved as second order ode using Kovacic algorithm

Time used: 0.542 (sec)

Writing the ode as

$$16x^2y'' + \left(8x^3 + 4x^2 + 24x\right) y' + \left(18x^2 + 5x + 1\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 16x^2 \\ B &= 8x^3 + 4x^2 + 24x \\ C &= 18x^2 + 5x + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 + 4x^3 - 31x^2 - 8x - 16 \\ t &= 64x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 242: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 4 \\
&= -2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{16} + \frac{x}{16} - \frac{31}{64} - \frac{1}{8x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} + \frac{1}{8} - \frac{1}{x} + \frac{1}{4x^2} - \frac{21}{8x^3} + \frac{37}{16x^4} - \frac{377}{32x^5} + \frac{1137}{64x^6} + \cdots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{1}{8} + \frac{x}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{64} + \frac{1}{16}x + \frac{1}{16}x^2$$

This shows that the coefficient of 1 in the above is $\frac{1}{64}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2} \\ &= Q + \frac{R}{64x^2} \\ &= \left(\frac{1}{16}x^2 + \frac{1}{16}x - \frac{31}{64}\right) + \left(\frac{-8x - 16}{64x^2}\right) \\ &= \frac{x^2}{16} + \frac{x}{16} - \frac{31}{64} + \frac{-8x - 16}{64x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{31}{64}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{31}{64}\right) - \left(\frac{1}{64}\right) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{8}+\frac{x}{4} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a}-v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{4}}-1\right) &&= -\frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a}-v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{4}}-1\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^4+4x^3-31x^2-8x-16}{64x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{1}{8}+\frac{x}{4}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + (-)\left(\frac{1}{8} + \frac{x}{4}\right) \\
&= \frac{1}{2x} - \frac{1}{8} - \frac{x}{4} \\
&= \frac{1}{2x} - \frac{1}{8} - \frac{x}{4}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} - \frac{1}{8} - \frac{x}{4}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{4}\right) + \left(\frac{1}{2x} - \frac{1}{8} - \frac{x}{4}\right)^2 - \left(\frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2}\right)\right) = 0
$$

$$
0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{8} - \frac{x}{4}\right) dx} \\
&= \sqrt{x}\, \mathrm{e}^{-\frac{x(x+1)}{8}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{8x^3 + 4x^2 + 24x}{16x^2} \, dx} \\
&= z_1 e^{-\frac{x^2}{8} - \frac{x}{8} - \frac{3\ln(x)}{4}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x(x+1)}{8}}}{x^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{e^{-\frac{x(x+1)}{4}}}{x^{1/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} dx}}{y_1^2} dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{8x^3+4x^2+24x}{16x^2} dx}}{(y_1)^2} dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{4}-\frac{x}{4}-\frac{3\ln(x)}{2}}}{(y_1)^2} dx \\ &= y_1 \left(\int e^{-\frac{x^2}{4}-\frac{x}{4}-\frac{3\ln(x)}{2}} \sqrt{x}\, e^{\frac{x(x+1)}{2}} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{e^{-\frac{x(x+1)}{4}}}{x^{1/4}} \right) + c_2 \left(\frac{e^{-\frac{x(x+1)}{4}}}{x^{1/4}} \left(\int e^{-\frac{x^2}{4}-\frac{x}{4}-\frac{3\ln(x)}{2}} \sqrt{x}\, e^{\frac{x(x+1)}{2}} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.129.2 Maple step by step solution

Let's solve

$16x^2 \left(\frac{d}{dx} y' \right) + 4x(2x^2 + x + 6) y' + (18x^2 + 5x + 1) y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$

- Isolate 2nd derivative

  $\frac{d}{dx} y' = -\frac{(18x^2+5x+1)y}{16x^2} - \frac{(2x^2+x+6)y'}{4x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx} y' + \frac{(2x^2+x+6)y'}{4x} + \frac{(18x^2+5x+1)y}{16x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{2x^2+x+6}{4x}, P_3(x) = \frac{18x^2+5x+1}{16x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{3}{2}$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = \frac{1}{16}$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $16x^2\left(\frac{d}{dx}y'\right) + 4x(2x^2 + x + 6)\, y' + (18x^2 + 5x + 1)\, y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$
  - Shift index using $k- >k + 1 - m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k + 1 - m + r)\, x^{k+r}$
  - Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r}$

    Rewrite ODE with series expansions

$$a_0(1+4r)^2 x^r + \left(a_1(5+4r)^2 + a_0(5+4r)\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(4k+4r+1)^2 + a_{k-1}(4k+4r+1) \right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+4r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = -\frac{1}{4}$
- Each term must be 0
  $a_1(5+4r)^2 + a_0(5+4r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = -\frac{a_0}{5+4r}$
- Each term in the series must be 0, giving the recursion relation
  $a_k(4k+4r+1)^2 + (4k+4r+1)(2a_{k-2} + a_{k-1}) = 0$
- Shift index using $k- >k+2$
  $a_{k+2}(4k+4r+9)^2 + (4k+4r+9)(2a_k + a_{k+1}) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{2a_k + a_{k+1}}{4k+4r+9}$
- Recursion relation for $r = -\frac{1}{4}$
  $a_{k+2} = -\frac{2a_k + a_{k+1}}{4k+8}$
- Solution for $r = -\frac{1}{4}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{4}}, a_{k+2} = -\frac{2a_k + a_{k+1}}{4k+8}, a_1 = -\frac{a_0}{4}\right]$

Solve

$$9x^2(1+x)\,y''+3x\left(-x^2+11x+5\right)y'+\left(-7x^2+16x+1\right)y=0$$

1.130.1 Solved as second order ode using Kovacic algorithm

Time used: 0.416 (sec)

Writing the ode as

$$\left(9x^3+9x^2\right)y''+\left(-3x^3+33x^2+15x\right)y'+\left(-7x^2+16x+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=9x^3+9x^2\\B&=-3x^3+33x^2+15x\\C&=-7x^2+16x+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 + 6x^3 + 3x^2 - 18x - 9}{36\,(x^2 + x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 + 6x^3 + 3x^2 - 18x - 9 \\ t &= 36(x^2 + x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 + 6x^3 + 3x^2 - 18x - 9}{36\,(x^2 + x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 244: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{7}{36\,(1+x)^2} + \frac{1}{9+9x} - \frac{1}{4x^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{6} + \frac{1}{3x} - \frac{5}{6x^2} + \frac{5}{6x^3} - \frac{7}{3x^4} + \frac{41}{6x^5} - \frac{149}{6x^6} + \frac{277}{3x^7} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{6}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{6}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading

coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t}\\
&= \frac{x^4+6x^3+3x^2-18x-9}{36x^4+72x^3+36x^2}\\
&= Q + \frac{R}{36x^4+72x^3+36x^2}\\
&= \left(\frac{1}{36}\right) + \left(\frac{4x^3+2x^2-18x-9}{36x^4+72x^3+36x^2}\right)\\
&= \frac{1}{36} + \frac{4x^3+2x^2-18x-9}{36x^4+72x^3+36x^2}
\end{aligned}
$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is 4. Dividing this by leading coefficient in t which is 36 gives $\frac{1}{9}$. Now b can be found.

$$
\begin{aligned}
b &= \left(\frac{1}{9}\right) - (0)\\
&= \frac{1}{9}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{6}\\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{9}}{\frac{1}{6}} - 0\right) &&= \frac{1}{3}\\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{9}}{\frac{1}{6}} - 0\right) &&= -\frac{1}{3}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4+6x^3+3x^2-18x-9}{36\left(x^2+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$\frac{1}{3}$	$-\frac{1}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to

determine possible non negative integer d from these using

$$d = \alpha_{\infty}^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_{\infty}^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_{\infty}^{+} = \frac{1}{3}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\ &= \frac{1}{3} - \left(\frac{1}{3}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (+)[\sqrt{r}]_{\infty} \\ &= -\frac{1}{6\,(1+x)} + \frac{1}{2x} + \left(\frac{1}{6}\right) \\ &= -\frac{1}{6\,(1+x)} + \frac{1}{2x} + \frac{1}{6} \\ &= -\frac{1}{6+6x} + \frac{1}{2x} + \frac{1}{6} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{6\,(1+x)} + \frac{1}{2x} + \frac{1}{6}\right)(0) + \left(\left(\frac{1}{6\,(1+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{1}{6\,(1+x)} + \frac{1}{2x} + \frac{1}{6}\right)^2 - \left(\frac{x^4 + 6x^3 +}{36\,(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{6(1+x)}+\frac{1}{2x}+\frac{1}{6}\right)dx} \\
&= \frac{\sqrt{x}\,\mathrm{e}^{\frac{x}{6}}}{(1+x)^{1/6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x^3+33x^2+15x}{9x^3+9x^2}\, dx} \\
&= z_1 e^{\frac{x}{6}-\frac{7\ln(1+x)}{6}-\frac{5\ln(x)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x}{6}}}{(1+x)^{7/6}\, x^{5/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^{\frac{x}{3}}}{(1+x)^{4/3}\, x^{1/3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x^3+33x^2+15x}{9x^3+9x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x}{3}-\frac{7\ln(1+x)}{3}-\frac{5\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \mathrm{e}^{\frac{x}{3}-\frac{7\ln(1+x)}{3}-\frac{5\ln(x)}{3}} (1+x)^{8/3}\, x^{2/3} \mathrm{e}^{-\frac{2x}{3}}\, dx\right)
\end{aligned}
$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{e^{\frac{x}{3}}}{(1+x)^{4/3} x^{1/3}}\right) + c_2 \left(\frac{e^{\frac{x}{3}}}{(1+x)^{4/3} x^{1/3}} \left(\int e^{\frac{x}{3} - \frac{7\ln(1+x)}{3} - \frac{5\ln(x)}{3}} (1+x)^{8/3} x^{2/3} e^{-\frac{2x}{3}} dx\right)\right)$$

Will add steps showing solving for IC soon.

1.130.2 Maple step by step solution

Let's solve
$9x^2(1+x)\left(\frac{d}{dx}y'\right) + 3x(-x^2+11x+5)\,y' + (-7x^2+16x+1)\,y = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d}{dx}y'$
- Isolate 2nd derivative
  $\frac{d}{dx}y' = \frac{(7x^2-16x-1)y}{9x^2(1+x)} + \frac{(x^2-11x-5)y'}{3x(1+x)}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d}{dx}y' - \frac{(x^2-11x-5)y'}{3x(1+x)} - \frac{(7x^2-16x-1)y}{9x^2(1+x)} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{x^2-11x-5}{3x(1+x)}, P_3(x) = -\frac{7x^2-16x-1}{9x^2(1+x)}\right]$
  - $(1+x)\cdot P_2(x)$ is analytic at $x=-1$
    $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1} = \frac{7}{3}$
  - $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$
    $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$
  - $x=-1$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = -1$

- Multiply by denominators
  $9x^2(1+x)\left(\frac{d}{dx}y'\right) - 3x(x^2-11x-5)\,y' + (-7x^2+16x+1)\,y = 0$
- Change variables using $x = u-1$ so that the regular singular point is at $u=0$
  $(9u^3-18u^2+9u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (-3u^3+42u^2-60u+21)\left(\frac{d}{du}y(u)\right) + (-7u^2+30u-22)\,y(u) =$
- Assume series solution for $y(u)$

$$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..2$

$$u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$$

- Shift index using $k- >k - m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..3$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k + 2 - m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0 r(4+3r)\, u^{-1+r} + \left(3a_1(1+r)(7+3r) - 2a_0\left(9r^2+21r+11\right)\right) u^r + \left(3a_2(2+r)(10+3r) - 2a\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $3r(4+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, -\frac{4}{3}\right\}$
- The coefficients of each power of u must be 0
  $[3a_1(1+r)(7+3r) - 2a_0(9r^2+21r+11) = 0, 3a_2(2+r)(10+3r) - 2a_1(9r^2+39r+41) + 3a$
- Solve for the dependent coefficient(s)
  $\left\{a_1 = \frac{2a_0(9r^2+21r+11)}{3(3r^2+10r+7)}, a_2 = \frac{a_0(243r^4+1593r^3+3699r^2+3567r+1174)}{9(9r^4+78r^3+241r^2+312r+140)}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $9(-2a_k + a_{k-1} + a_{k+1})\, k^2 + 3(6(-2a_k + a_{k-1} + a_{k+1})\, r - 14a_k - a_{k-2} + 5a_{k-1} + 10a_{k+1})\, k + 9($
- Shift index using $k- >k + 2$

$$9(-2a_{k+2}+a_{k+1}+a_{k+3})(k+2)^2+3(6(-2a_{k+2}+a_{k+1}+a_{k+3})r-14a_{k+2}-a_k+5a_{k+1}+10a_{k}$$

- Recursion relation that defines series solution to ODE

$$a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}+18kra_{k+1}-36kra_{k+2}+9r^2a_{k+1}-18r^2a_{k+2}-3ka_k+51ka_{k+1}-114ka_{k+2}-3ra_k+51ra_{k+1}-114ra}{3(3k^2+6kr+3r^2+22k+22r+39)}$$

- Recursion relation for $r=0$

$$a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}-3ka_k+51ka_{k+1}-114ka_{k+2}-7a_k+72a_{k+1}-178a_{k+2}}{3(3k^2+22k+39)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^k, a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}-3ka_k+51ka_{k+1}-114ka_{k+2}-7a_k+72a_{k+1}-178a_{k+2}}{3(3k^2+22k+39)}, a_1=\frac{22a_0}{21}, a_2=\right.$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^k, a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}-3ka_k+51ka_{k+1}-114ka_{k+2}-7a_k+72a_{k+1}-178a_{k+2}}{3(3k^2+22k+39)}, a_1=\frac{22a_0}{21},\right.$$

- Recursion relation for $r=-\frac{4}{3}$

$$a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}-3ka_k+27ka_{k+1}-66ka_{k+2}-3a_k+20a_{k+1}-58a_{k+2}}{3(3k^2+14k+15)}$$

- Solution for $r=-\frac{4}{3}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k-\frac{4}{3}}, a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}-3ka_k+27ka_{k+1}-66ka_{k+2}-3a_k+20a_{k+1}-58a_{k+2}}{3(3k^2+14k+15)}, a_1=\frac{2a_0}{3}, a_2=\right.$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^{k-\frac{4}{3}}, a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}-3ka_k+27ka_{k+1}-66ka_{k+2}-3a_k+20a_{k+1}-58a_{k+2}}{3(3k^2+14k+15)}, a_1=\frac{2a_0}{3},\right.$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k(1+x)^k\right)+\left(\sum_{k=0}^{\infty}b_k(1+x)^{k-\frac{4}{3}}\right), a_{k+3}=-\frac{9k^2a_{k+1}-18k^2a_{k+2}-3ka_k+51ka_{k+1}-114ka_{k+2}-7a}{3(3k^2+22k+39)}\right.$$

Solve

$$36x^2(1-2x)\,y''+24x(1-9x)\,y'+(1-70x)\,y=0$$

1.131.1 Solved as second order ode using Kovacic algorithm

Time used: 0.407 (sec)

Writing the ode as

$$\left(-72x^3+36x^2\right)y''+\left(-216x^2+24x\right)y'+(1-70x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-72x^3+36x^2\\ B&=-216x^2+24x\\ C&=1-70x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-32x^2 + 48x - 9}{36 \left(2x^2 - x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -32x^2 + 48x - 9 \\ t &= 36\left(2x^2 - x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-32x^2 + 48x - 9}{36 \left(2x^2 - x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 246: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{1}{3x} + \frac{7}{36\left(x - \frac{1}{2}\right)^2} - \frac{1}{3\left(x - \frac{1}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{6}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading

coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-32x^2 + 48x - 9}{36 (2x^2 - x)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{2}{9}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{2}{3} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{3}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-32x^2 + 48x - 9}{36 (2x^2 - x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{2}{3}$	$\frac{1}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{3}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^+ + \alpha_{c_2}^-) \\
&= \frac{1}{3} - \left(\frac{1}{3}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} - \frac{1}{6\left(x-\frac{1}{2}\right)} + (-)\,(0) \\
&= \frac{1}{2x} - \frac{1}{6\left(x-\frac{1}{2}\right)} \\
&= \frac{-3+4x}{12x^2-6x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} - \frac{1}{6\left(x-\frac{1}{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{6\left(x-\frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{1}{6\left(x-\frac{1}{2}\right)}\right)^2 - \left(\frac{-32x^2+48x-9}{36\left(2x^2-x\right)^2}\right.\right.
$$

$$
0 =
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{6\left(x-\frac{1}{2}\right)}\right) dx} \\
&= \frac{\sqrt{x}}{(-1+2x)^{1/6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-216x^2+24x}{-72x^3+36x^2} \, dx} \\
&= z_1 e^{-\frac{7\ln(-1+2x)}{6} - \frac{\ln(x)}{3}} \\
&= z_1 \left(\frac{1}{(-1+2x)^{7/6}\, x^{1/3}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{x^{1/6}}{(-1+2x)^{4/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-216x^2+24x}{-72x^3+36x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(-1+2x)}{3}-\frac{2\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(3(-1+2x)^{1/3} + \frac{\ln\left((-1+2x)^{2/3}-(-1+2x)^{1/3}+1\right)}{2} \right. \\
&\quad \left. - \sqrt{3}\arctan\left(\frac{\left(-1+2(-1+2x)^{1/3}\right)\sqrt{3}}{3}\right) - \ln\left((-1+2x)^{1/3}+1\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/6}}{(-1+2x)^{4/3}}\right) \\
&\quad + c_2 \left(\frac{x^{1/6}}{(-1+2x)^{4/3}} \left(3(-1+2x)^{1/3} + \frac{\ln\left((-1+2x)^{2/3}-(-1+2x)^{1/3}+1\right)}{2} - \sqrt{3}\arctan\left(\frac{\left(-1+2(-\right.}{}\right.\right.\right.
\end{aligned}$$

Will add steps showing solving for IC soon.

1.131.2 Maple step by step solution

Let's solve

$36x^2(1-2x)\left(\frac{d}{dx}y'\right)+24x(1-9x)\,y'+(1-70x)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{(70x-1)y}{36x^2(-1+2x)}-\frac{2(-1+9x)y'}{3x(-1+2x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{2(-1+9x)y'}{3x(-1+2x)}+\frac{(70x-1)y}{36x^2(-1+2x)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{2(-1+9x)}{3x(-1+2x)},P_3(x)=\frac{70x-1}{36x^2(-1+2x)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$(x\cdot P_2(x))\bigg|_{x=0}=\frac{2}{3}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$(x^2\cdot P_3(x))\bigg|_{x=0}=\frac{1}{36}$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$36x^2(-1+2x)\left(\frac{d}{dx}y'\right)+24x(-1+9x)\,y'+(70x-1)\,y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..1$

$x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

$x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(-1+6r)^2\, x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(6k+6r-1)^2 + 2a_{k-1}(6k+1+6r)\,(6k+6r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-(-1+6r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = \frac{1}{6}$$

- Each term in the series must be 0, giving the recursion relation

$$-36\left(k+r-\frac{1}{6}\right)\left(\left(-2k-2r-\frac{1}{3}\right) a_{k-1} + a_k\left(k+r-\frac{1}{6}\right)\right) = 0$$

- Shift index using $k->k+1$

$$-36\left(k+\frac{5}{6}+r\right)\left(\left(-2k-\frac{7}{3}-2r\right) a_k + a_{k+1}\left(k+\frac{5}{6}+r\right)\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{2(6k+6r+7)a_k}{6k+6r+5}$$

- Recursion relation for $r = \frac{1}{6}$

$$a_{k+1} = \frac{2(6k+8)a_k}{6k+6}$$

- Solution for $r = \frac{1}{6}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{6}}, a_{k+1} = \frac{2(6k+8)a_k}{6k+6}\right]$$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 134
Date solved : `Monday, October 21, 2024 at 05:04:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''-x(3-x)\,y'+4y=0$$

1.132.1 Solved as second order ode using Kovacic algorithm

Time used: 0.283 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(x^2-3x\right)y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2(1+x)\\B&=x^2-3x\\C&=4\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-x^2 - 10x - 1}{4\left(x^2 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -x^2 - 10x - 1 \\
t &= 4\left(x^2 + x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-x^2 - 10x - 1}{4\left(x^2 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 248: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{x} + \frac{2}{(1+x)^2} - \frac{1}{4x^2} + \frac{2}{1+x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 10x - 1}{4(x^2 + x)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-x^2-10x-1}{4\left(x^2+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-1	2	0	2	-1
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right) \\
&= \frac{1}{2}-\left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{1+x} + \frac{1}{2x} + (-)(0) \\
&= -\frac{1}{1+x} + \frac{1}{2x} \\
&= -\frac{x-1}{2x(1+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{1+x} + \frac{1}{2x}\right)(1) + \left(\left(\frac{1}{(1+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{1}{1+x} + \frac{1}{2x}\right)^2 - \left(\frac{-x^2-10x-1}{4(x^2+x)^2}\right)\right) = 0
$$

$$
\frac{1+a_0}{x(1+x)} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = -1\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x - 1
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x-1)\, e^{\int \left(-\frac{1}{1+x} + \frac{1}{2x}\right) dx} \\
&= (x-1)\, e^{\frac{\ln(x)}{2} - \ln(1+x)} \\
&= \frac{(x-1)\sqrt{x}}{1+x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2-3x}{x^2(1+x)}\,dx} \\
&= z_1 e^{\frac{3\ln(x)}{2}-2\ln(1+x)} \\
&= z_1\left(\frac{x^{3/2}}{(1+x)^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^2(x-1)}{(1+x)^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2-3x}{x^2(1+x)}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3\ln(x)-4\ln(1+x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{4}{x-1}+\ln(x)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^2(x-1)}{(1+x)^3}\right) + c_2\left(\frac{x^2(x-1)}{(1+x)^3}\left(-\frac{4}{x-1}+\ln(x)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.132.2 Maple step by step solution

Let's solve

$x^2(1+x)\left(\frac{d}{dx}y'\right)-x(3-x)\,y'+4y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{4y}{x^2(1+x)}-\frac{(x-3)y'}{x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(x-3)y'}{x(1+x)}+\frac{4y}{x^2(1+x)}=0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=\frac{x-3}{x(1+x)},P_3(x)=\frac{4}{x^2(1+x)}\right]$

- ○ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1}=4$

- ○ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

- ○ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $x^2(1+x)\left(\frac{d}{dx}y'\right)+x(x-3)\,y'+4y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^3-2u^2+u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(u^2-5u+4)\left(\frac{d}{du}y(u)\right)+4y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

$$u^{m}\cdot \left(\frac{d}{d u}y \left(u \right)\right)=\sum_{k =-1+m}^{\infty} a_{k +1-m} \left(k +1-m +r \right) u^{k +r}$$

- Convert $u^{m}\cdot \left(\frac{d}{d u}\frac{d}{d u}y \left(u \right)\right)$ to series expansion for $m =1..3$

$$u^{m}\cdot \left(\frac{d}{d u}\frac{d}{d u}y \left(u \right)\right)=\sum_{k =0}^{\infty} a_{k} \left(k +r \right) \left(k +r -1\right) u^{k +r -2+m}$$

- Shift index using $k - >k +2-m$

$$u^{m}\cdot \left(\frac{d}{d u}\frac{d}{d u}y \left(u \right)\right)=\sum_{k =-2+m}^{\infty} a_{k +2-m} \left(k +2-m +r \right) \left(k +1-m +r \right) u^{k +r}$$

Rewrite ODE with series expansions

$$a_{0} r \left(3+r \right) u^{-1+r}+\left(a_{1} \left(1+r \right) \left(4+r \right)-a_{0} \left(2 r^{2}+3 r -4\right)\right) u^{r}+\left(\sum_{k =1}^{\infty} \left(a_{k +1} \left(k +1+r \right) \left(k +4+r \right)\right.\right.$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

$$r \left(3+r \right)=0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{-3, 0\right\}$$

- Each term must be 0

$$a_{1} \left(1+r \right) \left(4+r \right)-a_{0} \left(2 r^{2}+3 r -4\right)=0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k +1} \left(k +1+r \right) \left(k +4+r \right)-a_{k} \left(2 k^{2}+4 k r +2 r^{2}+3 k +3 r -4\right)+a_{k -1} \left(k +r -1\right)^{2}=0$$

- Shift index using $k - >k +1$

$$a_{k +2} \left(k +2+r \right) \left(k +5+r \right)-a_{k +1} \left(2 \left(k +1\right)^{2}+4 \left(k +1\right) r +2 r^{2}+3 k -1+3 r \right)+a_{k} \left(k +r \right)^{2}=$$

- Recursion relation that defines series solution to ODE

$$a_{k +2}=-\frac{k^{2} a_{k}-2 k^{2} a_{k +1}+2 k r a_{k}-4 k r a_{k +1}+r^{2} a_{k}-2 r^{2} a_{k +1}-7 k a_{k +1}-7 r a_{k +1}-a_{k +1}}{\left(k +2+r \right) \left(k +5+r \right)}$$

- Recursion relation for $r =-3$

$$a_{k +2}=-\frac{k^{2} a_{k}-2 k^{2} a_{k +1}-6 k a_{k}+5 k a_{k +1}+9 a_{k}+2 a_{k +1}}{\left(k -1\right) \left(k +2\right)}$$

- Series not valid for $r =-3$, division by 0 in the recursion relation at $k =1$

$$a_{k +2}=-\frac{k^{2} a_{k}-2 k^{2} a_{k +1}-6 k a_{k}+5 k a_{k +1}+9 a_{k}+2 a_{k +1}}{\left(k -1\right) \left(k +2\right)}$$

- Recursion relation for $r =0$

$$a_{k +2}=-\frac{k^{2} a_{k}-2 k^{2} a_{k +1}-7 k a_{k +1}-a_{k +1}}{\left(k +2\right) \left(k +5\right)}$$

- Solution for $r =0$

$$\left[y \left(u \right)=\sum_{k =0}^{\infty} a_{k} u^{k}, a_{k +2}=-\frac{k^{2} a_{k}-2 k^{2} a_{k +1}-7 k a_{k +1}-a_{k +1}}{\left(k +2\right) \left(k +5\right)}, 4 a_{1}+4 a_{0}=0\right]$$

- Revert the change of variables $u =1+x$

$$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - 7k a_{k+1} - a_{k+1}}{(k+2)(k+5)}, 4a_1 + 4a_0 = 0\right]$$

1.133 problem 135

Internal problem ID [8271]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 135
Date solved : `Monday, October 21, 2024 at 05:04:57 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''-x(5-4x)\,y'+(9-4x)\,y=0$$

1.133.1 Solved as second order ode using Kovacic algorithm

Time used: 0.267 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+\left(4x^2-5x\right)y'+(9-4x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -2x^3+x^2 \\ B &= 4x^2-5x \\ C &= 9-4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{8x - 1}{4(2x^2 - x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 8x - 1 \\ t &= 4(2x^2 - x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{8x - 1}{4(2x^2 - x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 250: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 1 \\ &= 3 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 3 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 3 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{x} - \frac{1}{4x^2} + \frac{3}{4\left(x - \frac{1}{2}\right)^2} - \frac{1}{x - \frac{1}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $3 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{8x - 1}{4 \left(2x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
3	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\ &= 0 - (0) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} - \frac{1}{2 \left(x - \frac{1}{2}\right)} + (0) \\ &= \frac{1}{2x} - \frac{1}{2 \left(x - \frac{1}{2}\right)} \\ &= -\frac{1}{2x \left(-1 + 2x\right)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{1}{2\left(x - \frac{1}{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{2\left(x - \frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{1}{2\left(x - \frac{1}{2}\right)}\right)^2 - \left(\frac{8x - 1}{4\left(2x^2 - x\right)^2}\right)\right) =$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{2\left(x - \frac{1}{2}\right)}\right) dx} \\
&= \frac{\sqrt{x}}{\sqrt{-1 + 2x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{4x^2 - 5x}{-2x^3 + x^2} \, dx} \\
&= z_1 e^{-\frac{3 \ln(-1+2x)}{2} + \frac{5 \ln(x)}{2}} \\
&= z_1 \left(\frac{x^{5/2}}{(-1 + 2x)^{3/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^3}{(-1 + 2x)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x^2-5x}{-2x^3+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3\ln(-1+2x)+5\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(2x - \ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^3}{(-1+2x)^2}\right) + c_2\left(\frac{x^3}{(-1+2x)^2}(2x - \ln(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.133.2 Maple step by step solution

Let's solve

$x^2(1-2x)\left(\frac{d}{dx}y'\right) - x(5-4x)\,y' + (9-4x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(-9+4x)y}{x^2(-1+2x)} + \frac{(4x-5)y'}{x(-1+2x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{(4x-5)y'}{x(-1+2x)} + \frac{(-9+4x)y}{x^2(-1+2x)} = 0$

□ Check to see if x_0 is a regular singular point

1.134 problem 136

Internal problem ID [8272]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 136
Date solved : `Monday, October 21, 2024 at 05:04:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(2+x)\,y''+x^2y'+(1-x)\,y=0$$

1.134.1 Solved as second order ode using Kovacic algorithm

Time used: 0.262 (sec)

Writing the ode as

$$\left(2x^3+4x^2\right)y''+x^2y'+(1-x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+4x^2 \\ B &= x^2 \\ C &= 1-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{5x^2 + 8x - 16}{16\left(x^2 + 2x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 5x^2 + 8x - 16 \\
t &= 16\left(x^2 + 2x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{5x^2 + 8x - 16}{16\left(x^2 + 2x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 252: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{8x} - \frac{1}{4x^2} - \frac{3}{16(2+x)^2} - \frac{3}{8(2+x)}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}\end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5x^2 + 8x - 16}{16(x^2 + 2x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{5x^2 + 8x - 16}{16\left(x^2 + 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{3}{4}$	$\frac{1}{4}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{5}{4} - \left(\frac{5}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{3}{4\,(2+x)} + \frac{1}{2x} + (0) \\
&= \frac{3}{4\,(2+x)} + \frac{1}{2x} \\
&= \frac{5x+4}{4x\,(2+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{3}{4\,(2+x)} + \frac{1}{2x}\right)(0) + \left(\left(-\frac{3}{4\,(2+x)^2} - \frac{1}{2x^2}\right) + \left(\frac{3}{4\,(2+x)} + \frac{1}{2x}\right)^2 - \left(\frac{5x^2+8x-16}{16\,(x^2+2x)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{3}{4(2+x)} + \frac{1}{2x}\right) dx} \\
&= (2+x)^{3/4}\sqrt{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2}{2x^3+4x^2}\, dx} \\
&= z_1 e^{-\frac{\ln(2+x)}{4}} \\
&= z_1\left(\frac{1}{(2+x)^{1/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \sqrt{2+x}\,\sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2}{2x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(2+x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{2} + \frac{1}{\sqrt{2+x}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{2+x}\,\sqrt{x}\right) + c_2\left(\sqrt{2+x}\,\sqrt{x}\left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{2} + \frac{1}{\sqrt{2+x}}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.134.2 Maple step by step solution

Let's solve

$2x^2(2+x)\left(\frac{d}{dx}y'\right) + x^2y' + (1-x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(x-1)y}{2x^2(2+x)} - \frac{y'}{2(2+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{y'}{2(2+x)} - \frac{(x-1)y}{2x^2(2+x)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{2(2+x)}, P_3(x) = -\frac{x-1}{2x^2(2+x)}\right]$
  - $(2+x) \cdot P_2(x)$ is analytic at $x = -2$

    $\left((2+x) \cdot P_2(x)\right)\Big|_{x=-2} = \frac{1}{2}$
  - $(2+x)^2 \cdot P_3(x)$ is analytic at $x = -2$

    $\left((2+x)^2 \cdot P_3(x)\right)\Big|_{x=-2} = 0$
  - $x = -2$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -2$

- Multiply by denominators

  $2x^2(2+x)\left(\frac{d}{dx}y'\right) + x^2y' + (1-x)\,y = 0$

- Change variables using $x = u-2$ so that the regular singular point is at $u = 0$

  $(2u^3 - 8u^2 + 8u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (u^2 - 4u + 4)\left(\frac{d}{du}y(u)\right) + (3-u)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

    $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$
  - Shift index using $k- >k-m$

    $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $4a_0 r(-1+2r)\, u^{-1+r} + (4a_1(1+r)(1+2r) - a_0(8r^2-4r-3))\, u^r + \left(\sum_{k=1}^{\infty} (4a_{k+1}(k+1+r)(2k\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $4r(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$

- Each term must be 0

  $4a_1(1+r)(1+2r) - a_0(8r^2-4r-3) = 0$

- Each term in the series must be 0, giving the recursion relation

  $2(-4a_k + a_{k-1} + 4a_{k+1})\, k^2 + (4(-4a_k + a_{k-1} + 4a_{k+1})\, r + 4a_k - 5a_{k-1} + 12a_{k+1})\, k + 2(-4a_k +$

- Shift index using $k- >k+1$

  $2(-4a_{k+1} + a_k + 4a_{k+2})\, (k+1)^2 + (4(-4a_{k+1} + a_k + 4a_{k+2})\, r + 4a_{k+1} - 5a_k + 12a_{k+2})\, (k+1) -$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 4kra_k - 16kra_{k+1} + 2r^2a_k - 8r^2a_{k+1} - ka_k - 12ka_{k+1} - ra_k - 12ra_{k+1} - a_k - a_{k+1}}{4(2k^2+4kr+2r^2+7k+7r+6)}$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k - a_{k+1}}{4(2k^2+7k+6)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k - a_{k+1}}{4(2k^2+7k+6)}, 4a_1 + 3a_0 = 0\right]$

- Revert the change of variables $u = 2 + x$

  $\left[y = \sum_{k=0}^{\infty} a_k (2+x)^k, a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k - a_{k+1}}{4(2k^2+7k+6)}, 4a_1 + 3a_0 = 0\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + ka_k - 20ka_{k+1} - a_k - 9a_{k+1}}{4(2k^2+9k+10)}$

- Solution for $r = \frac{1}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + ka_k - 20ka_{k+1} - a_k - 9a_{k+1}}{4(2k^2+9k+10)}, 12a_1 + 3a_0 = 0\right]$

- Revert the change of variables $u = 2+x$

$$\left[y = \sum_{k=0}^{\infty} a_k (2+x)^{k+\frac{1}{2}}, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + k a_k - 20k a_{k+1} - a_k - 9a_{k+1}}{4(2k^2+9k+10)}, 12a_1 + 3a_0 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (2+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (2+x)^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} - k a_k - 12k a_{k+1} - a_k - a_{k+1}}{4(2k^2+7k+6)}, 4a_1 +$$

Solve

$$2x^2(1+x)\,y''-x(6-x)\,y'+(8-x)\,y=0$$

1.135.1 Solved as second order ode using Kovacic algorithm

Time used: 0.265 (sec)

Writing the ode as

$$\left(2x^3+2x^2\right)y''+\left(x^2-6x\right)y'+(8-x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+2x^2 \\ B &= x^2-6x \\ C &= 8-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5x^2 - 20x - 4}{16\left(x^2 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 5x^2 - 20x - 4$$
$$t = 16\left(x^2 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5x^2 - 20x - 4}{16\left(x^2 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 254: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{4x} + \frac{3}{4(1+x)} - \frac{1}{4x^2} + \frac{21}{16(1+x)^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}\end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5x^2 - 20x - 4}{16(x^2 + x)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{5}{4}\\ \alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{5x^2-20x-4}{16\left(x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=-\frac{1}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^- -\left(\alpha_{c_1}^- +\alpha_{c_2}^+\right)\\ &= -\frac{1}{4}-\left(-\frac{1}{4}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\ &= -\frac{3}{4\,(1+x)} + \frac{1}{2x} + (-)\,(0) \\ &= -\frac{3}{4\,(1+x)} + \frac{1}{2x} \\ &= -\frac{x-2}{4x\,(1+x)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{4\,(1+x)} + \frac{1}{2x}\right)(0) + \left(\left(\frac{3}{4\,(1+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{3}{4\,(1+x)} + \frac{1}{2x}\right)^2 - \left(\frac{5x^2-20x-4}{16\,(x^2+x)^2}\right)\right) =$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{3}{4(1+x)} + \frac{1}{2x}\right) dx} \\ &= \frac{\sqrt{x}}{(1+x)^{3/4}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2-6x}{2x^3+2x^2}\, dx} \\ &= z_1 e^{-\frac{7\ln(1+x)}{4} + \frac{3\ln(x)}{2}} \\ &= z_1 \left(\frac{x^{3/2}}{(1+x)^{7/4}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2}{(1+x)^{5/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2-6x}{2x^3+2x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(1+x)}{2}+3\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{2(1+x)^{3/2}}{3} + 2\sqrt{1+x} + \ln\left(\sqrt{1+x}-1\right) - \ln\left(1+\sqrt{1+x}\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^2}{(1+x)^{5/2}}\right) \\
&\quad + c_2 \left(\frac{x^2}{(1+x)^{5/2}} \left(\frac{2(1+x)^{3/2}}{3} + 2\sqrt{1+x} + \ln\left(\sqrt{1+x}-1\right) - \ln\left(1+\sqrt{1+x}\right)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.135.2 Maple step by step solution

Let's solve

$2x^2(1+x)\left(\frac{d}{dx}y'\right)-x(6-x)\,y'+(8-x)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=\frac{(x-8)y}{2x^2(1+x)}-\frac{(x-6)y'}{2x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(x-6)y'}{2x(1+x)}-\frac{(x-8)y}{2x^2(1+x)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{x-6}{2x(1+x)},P_3(x)=-\frac{x-8}{2x^2(1+x)}\right]$

- ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((1+x)\cdot P_2(x)\right)\bigg|_{x=-1}=\frac{7}{2}$

- ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\bigg|_{x=-1}=0$

- ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $2x^2(1+x)\left(\frac{d}{dx}y'\right)+x(x-6)\,y'+(8-x)\,y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(2u^3-4u^2+2u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(u^2-8u+7)\left(\frac{d}{du}y(u)\right)+(9-u)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ◦ Shift index using $k->k-m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(5+2r)\, u^{-1+r} + \left(a_1(1+r)\,(7+2r) - a_0(4r^2+4r-9)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)\,(2k+7+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(5+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{5}{2}\right\}$$

- Each term must be 0

$$a_1(1+r)\,(7+2r) - a_0(4r^2+4r-9) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(-4a_k + 2a_{k-1} + 2a_{k+1})\, k^2 + \left((-8a_k + 4a_{k-1} + 4a_{k+1})\, r - 4a_k - 5a_{k-1} + 9a_{k+1}\right) k + (-4a_k + 2a$$

- Shift index using $k->k+1$

$$(-4a_{k+1} + 2a_k + 2a_{k+2})\,(k+1)^2 + \left((-8a_{k+1} + 4a_k + 4a_{k+2})\, r - 4a_{k+1} - 5a_k + 9a_{k+2}\right)(k+1) +$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} + 4kra_k - 8kra_{k+1} + 2r^2a_k - 4r^2a_{k+1} - ka_k - 12ka_{k+1} - ra_k - 12ra_{k+1} - a_k + a_{k+1}}{2k^2 + 4kr + 2r^2 + 13k + 13r + 18}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k + a_{k+1}}{2k^2 + 13k + 18}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k + a_{k+1}}{2k^2 + 13k + 18}, 7a_1 + 9a_0 = 0\right]$$

- Revert the change of variables $u = 1 + x$

$$\left[y=\sum_{k=0}^{\infty} a_k (1+x)^k, a_{k+2}=-\frac{2k^2 a_k-4k^2 a_{k+1}-k a_k-12k a_{k+1}-a_k+a_{k+1}}{2k^2+13k+18}, 7a_1+9a_0=0\right]$$

- Recursion relation for $r=-\frac{5}{2}$

$$a_{k+2}=-\frac{2k^2 a_k-4k^2 a_{k+1}-11k a_k+8k a_{k+1}+14a_k+6a_{k+1}}{2k^2+3k-2}$$

- Solution for $r=-\frac{5}{2}$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k-\frac{5}{2}}, a_{k+2}=-\frac{2k^2 a_k-4k^2 a_{k+1}-11k a_k+8k a_{k+1}+14a_k+6a_{k+1}}{2k^2+3k-2}, -3a_1-6a_0=0\right]$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty} a_k (1+x)^{k-\frac{5}{2}}, a_{k+2}=-\frac{2k^2 a_k-4k^2 a_{k+1}-11k a_k+8k a_{k+1}+14a_k+6a_{k+1}}{2k^2+3k-2}, -3a_1-6a_0=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k (1+x)^k\right)+\left(\sum_{k=0}^{\infty} b_k (1+x)^{k-\frac{5}{2}}\right), a_{k+2}=-\frac{2k^2 a_k-4k^2 a_{k+1}-k a_k-12k a_{k+1}-a_k+a_{k+1}}{2k^2+13k+18}, 7a_1+\right.$$

Solve

$$x^2(1+2x)\,y''+x(5+9x)\,y'+(4+3x)\,y=0$$

1.136.1 Solved as second order ode using Kovacic algorithm

Time used: 0.286 (sec)

Writing the ode as

$$\left(2x^3+x^2\right)y''+\left(9x^2+5x\right)y'+(4+3x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+x^2 \\ B &= 9x^2+5x \\ C &= 4+3x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{21x^2 + 6x - 1}{4\left(2x^2 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 21x^2 + 6x - 1$$
$$t = 4\left(2x^2 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{21x^2 + 6x - 1}{4\left(2x^2 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 256: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{5}{2x} + \frac{5}{16\left(x + \frac{1}{2}\right)^2} - \frac{5}{2\left(x + \frac{1}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading

coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{21x^2 + 6x - 1}{4\left(2x^2 + x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{21x^2 + 6x - 1}{4\left(2x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{7}{4} - \left(\frac{7}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)} + (0) \\
&= \frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)} \\
&= \frac{1+7x}{4x^2+2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{5}{4\left(x+\frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)}\right)^2 - \left(\frac{21x^2+6x-1}{4\left(2x^2+x\right)^2}\right)\right)$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)}\right) dx} \\
&= \sqrt{x}\,(1+2x)^{5/4}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{9x^2+5x}{2x^3+x^2}\, dx} \\
&= z_1 e^{-\frac{5\ln(x)}{2} + \frac{\ln(1+2x)}{4}} \\
&= z_1 \left(\frac{(1+2x)^{1/4}}{x^{5/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(1+2x)^{3/2}}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{9x^2+5x}{2x^3+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-5\ln(x)+\frac{\ln(1+2x)}{2}}}{(y_1)^2}\,dx \\
&= y_1\left(\ln\left(\sqrt{1+2x}-1\right)+\frac{2}{3\,(1+2x)^{3/2}}+\frac{2}{\sqrt{1+2x}}-\ln\left(\sqrt{1+2x}+1\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{(1+2x)^{3/2}}{x^2}\right) \\
&\quad + c_2\left(\frac{(1+2x)^{3/2}}{x^2}\left(\ln\left(\sqrt{1+2x}-1\right)+\frac{2}{3\,(1+2x)^{3/2}}+\frac{2}{\sqrt{1+2x}}-\ln\left(\sqrt{1+2x}+1\right)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.136.2 Maple step by step solution

Let's solve

$x^2(1+2x)\left(\frac{d}{dx}y'\right)+x(5+9x)\,y'+(4+3x)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(4+3x)y}{x^2(1+2x)}-\frac{(5+9x)y'}{x(1+2x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(5+9x)y'}{x(1+2x)}+\frac{(4+3x)y}{x^2(1+2x)}=0$

□ Check to see if x_0 is a regular singular point

  - Convert $x^m\cdot y'$ to series expansion for $m=1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(2+r)^2\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+2)^2 + a_{k-1}(k+r+2)\,(2k-1+2r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(2+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = -2$$

- Each term in the series must be 0, giving the recursion relation

$$(k+r+2)\left(a_k(k+r+2) + a_{k-1}(2k-1+2r)\right) = 0$$

- Shift index using $k->k+1$

$$(k+r+3)\left(a_{k+1}(k+r+3) + a_k(2k+2r+1)\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k(2k+2r+1)}{k+r+3}$$

- Recursion relation for $r = -2$

$$a_{k+1} = -\frac{a_k(2k-3)}{k+1}$$

- Solution for $r = -2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+1} = -\frac{a_k(2k-3)}{k+1}\right]$$

1.137 problem 139

Internal problem ID [8275]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 139
Date solved : `Monday, October 21, 2024 at 05:05:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''-x(5+4x)\,y'+(9+4x)\,y=0$$

1.137.1 Solved as second order ode using Kovacic algorithm

Time used: 0.316 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+\left(-4x^2-5x\right)y'+(9+4x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -2x^3+x^2 \\ B &= -4x^2-5x \\ C &= 9+4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{32x^2 + 56x - 1}{4(2x^2 - x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 32x^2 + 56x - 1$$
$$t = 4(2x^2 - x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{32x^2 + 56x - 1}{4(2x^2 - x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 258: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4\left(x - \frac{1}{2}\right)^2} - \frac{13}{x - \frac{1}{2}} + \frac{13}{x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading

coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{32x^2 + 56x - 1}{4\left(2x^2 - x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{32x^2 + 56x - 1}{4\left(2x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right)\\ &= -1 - (-2)\\ &= 1\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)} + (-)(0) \\
&= \frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)} \\
&= \frac{-1-8x}{4x^2-2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)}\right)(1) + \left(\left(-\frac{1}{2x^2} + \frac{5}{2\left(x-\frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)}\right)^2 - \left(\frac{32x^2+56x-1}{4\left(2x^2-x\right)^2}\right)\right)
$$

$$
\frac{-1+8a_0}{x(-1+2x)} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{a_0 = \frac{1}{8}\right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + \frac{1}{8}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{1}{8}\right) e^{\int \left(\frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)}\right) dx} \\
&= \left(x + \frac{1}{8}\right) e^{\frac{\ln(x)}{2} - \frac{5\ln(-1+2x)}{2}} \\
&= \frac{\left(x+\frac{1}{8}\right)\sqrt{x}}{(-1+2x)^{5/2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x^2-5x}{-2x^3+x^2}\,dx} \\
&= z_1 e^{\frac{5\ln(x)}{2}-\frac{7\ln(-1+2x)}{2}} \\
&= z_1 \left(\frac{x^{5/2}}{(-1+2x)^{7/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^3\left(x+\frac{1}{8}\right)}{(-1+2x)^6}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^2-5x}{-2x^3+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{5\ln(x)-7\ln(-1+2x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{32x^3}{3} - 44x^2 + \frac{203x}{2} - 64\ln(x) - \frac{3125}{16(1+8x)}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^3\left(x+\frac{1}{8}\right)}{(-1+2x)^6}\right) + c_2\left(\frac{x^3\left(x+\frac{1}{8}\right)}{(-1+2x)^6}\left(\frac{32x^3}{3} - 44x^2 + \frac{203x}{2} - 64\ln(x) - \frac{3125}{16(1+8x)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.137.2 Maple step by step solution

Let's solve

$x^2(1-2x)\left(\frac{d}{dx}y'\right)-x(5+4x)\,y'+(9+4x)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=\frac{(9+4x)y}{x^2(-1+2x)}-\frac{(5+4x)y'}{x(-1+2x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(5+4x)y'}{x(-1+2x)}-\frac{(9+4x)y}{x^2(-1+2x)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{5+4x}{x(-1+2x)},P_3(x)=-\frac{9+4x}{x^2(-1+2x)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-5$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=9$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(-1+2x)\left(\frac{d}{dx}y'\right)+x(5+4x)\,y'+(-4x-9)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y$ to series expansion for $m=0..1$

    $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

    $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(-3+r)^2\, x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r-3)^2 + 2a_{k-1}(k+1+r)\,(k-2+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-(-3+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 3$$

- Each term in the series must be 0, giving the recursion relation

$$-a_k(k+r-3)^2 + 2a_{k-1}(k+1+r)\,(k-2+r) = 0$$

- Shift index using $k->k+1$

$$-a_{k+1}(k-2+r)^2 + 2a_k(k+r+2)\,(k+r-1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{2a_k(k+r+2)(k+r-1)}{(k-2+r)^2}$$

- Recursion relation for $r = 3$

$$a_{k+1} = \frac{2a_k(k+5)(k+2)}{(k+1)^2}$$

- Solution for $r = 3$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1} = \frac{2a_k(k+5)(k+2)}{(k+1)^2}\right]$$

1.138 problem 140

Internal problem ID [8276]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 140
Date solved : `Monday, October 21, 2024 at 05:05:03 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-x)\,y'' + x(7+x)\,y' + (9-x)\,y = 0$$

1.138.1 Solved as second order ode using Kovacic algorithm

Time used: 0.320 (sec)

Writing the ode as

$$\left(-x^3+x^2\right)y'' + \left(x^2+7x\right)y' + (9-x)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^3+x^2 \\ B &= x^2+7x \\ C &= 9-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-x^2 + 82x - 1}{4\left(x^2 - x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -x^2 + 82x - 1 \\
t &= 4\left(x^2 - x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-x^2 + 82x - 1}{4\left(x^2 - x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 260: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{20}{(-1+x)^2} - \frac{20}{-1+x} + \frac{20}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 20$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 5 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -4 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 + 82x - 1}{4(x^2 - x)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{-x^2+82x-1}{4\left(x^2-x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
1	2	0	5	-4

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{+}+\alpha_{c_2}^{-}\right)\\
&= \frac{1}{2}-\left(-\frac{7}{2}\right)\\
&= 4
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} - \frac{4}{-1+x} + (-)\,(0) \\
&= \frac{1}{2x} - \frac{4}{-1+x} \\
&= -\frac{1+7x}{2x\,(-1+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\left(12x^2 + 6x a_3 + 2a_2\right) + 2\left(\frac{1}{2x} - \frac{4}{-1+x}\right)\left(4x^3 + 3x^2 a_3 + 2a_2 x + a_1\right) + \left(\left(-\frac{1}{2x^2} + \frac{4}{(-1+x)^2}\right) + \left(\frac{1}{2x}\right.\right.
$$

$$
\frac{(a_3 - 16)\,x^3 + (4a_2 - 9a_3)}{x\,(}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 1, a_1 = 16, a_2 = 36, a_3 = 16\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x^4 + 16x^3 + 36x^2 + 16x + 1
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^4 + 16x^3 + 36x^2 + 16x + 1\right) e^{\int \left(\frac{1}{2x} - \frac{4}{-1+x}\right) dx} \\
&= \left(x^4 + 16x^3 + 36x^2 + 16x + 1\right) e^{\frac{\ln(x)}{2} - 4\ln(-1+x)} \\
&= \frac{\left(x^4 + 16x^3 + 36x^2 + 16x + 1\right)\sqrt{x}}{(-1+x)^4}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+7x}{-x^3+x^2}\,dx} \\
&= z_1 e^{-\frac{7\ln(x)}{2}+4\ln(-1+x)} \\
&= z_1\left(\frac{(-1+x)^4}{x^{7/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^4+16x^3+36x^2+16x+1}{x^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+7x}{-x^3+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-7\ln(x)+8\ln(-1+x)}}{(y_1)^2}\,dx \\
&= y_1\left(\ln(x) - \frac{20\left(-2x^3-\frac{15}{2}x^2-\frac{14}{3}x-\frac{5}{12}\right)}{x^4+16x^3+36x^2+16x+1}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^4+16x^3+36x^2+16x+1}{x^3}\right) \\
&\quad + c_2\left(\frac{x^4+16x^3+36x^2+16x+1}{x^3}\left(\ln(x) - \frac{20\left(-2x^3-\frac{15}{2}x^2-\frac{14}{3}x-\frac{5}{12}\right)}{x^4+16x^3+36x^2+16x+1}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.138.2 Maple step by step solution

Let's solve

$x^2(1-x)\left(\frac{d}{dx}y'\right)+x(7+x)\,y'+(9-x)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(-9+x)y}{x^2(-1+x)}+\frac{(7+x)y'}{x(-1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'-\frac{(7+x)y'}{x(-1+x)}+\frac{(-9+x)y}{x^2(-1+x)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=-\frac{7+x}{x(-1+x)},P_3(x)=\frac{-9+x}{x^2(-1+x)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=7$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=9$

- ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(-1+x)\left(\frac{d}{dx}y'\right)-x(7+x)\,y'+(-9+x)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..1$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx} y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0 (3+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(-a_k (k+r+3)^2 + a_{k-1} (k-2+r)^2\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-(3+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = -3$$

- Each term in the series must be 0, giving the recursion relation

$$-a_k (k+r+3)^2 + a_{k-1} (k-2+r)^2 = 0$$

- Shift index using $k->k+1$

$$-a_{k+1} (k+4+r)^2 + a_k (k+r-1)^2 = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k (k+r-1)^2}{(k+4+r)^2}$$

- Recursion relation for $r = -3$; series terminates at $k = 4$

$$a_{k+1} = \frac{a_k (k-4)^2}{(k+1)^2}$$

- Apply recursion relation for $k = 0$

$$a_1 = 16 a_0$$

- Apply recursion relation for $k = 1$

$$a_2 = \frac{9 a_1}{4}$$

- Express in terms of a_0

$$a_2 = 36 a_0$$

- Apply recursion relation for $k = 2$

$$a_3 = \frac{4 a_2}{9}$$

- Express in terms of a_0

$a_3 = 16a_0$

- Apply recursion relation for $k = 3$

  $a_4 = \frac{a_3}{16}$
- Express in terms of a_0

  $a_4 = a_0$
- Terminating series solution of the ODE for $r = -3$. Use reduction of order to find the second

  $y = a_0 \cdot (x^4 + 16x^3 + 36x^2 + 16x + 1)$

1.139 problem 141

Internal problem ID [8277]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 141
Date solved : `Monday, October 21, 2024 at 05:05:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x\left(-x^2+1\right)y' + \left(x^2+1\right)y = 0$$

1.139.1 Solved as second order ode using Kovacic algorithm

Time used: 0.301 (sec)

Writing the ode as

$$x^2y'' + \left(x^3-x\right)y' + \left(x^2+1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^3 - x \\ C &= x^2 + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 4x^2 - 1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^4 - 4x^2 - 1$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 262: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{4} - 1 - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{1}{x} - \frac{5}{4x^3} - \frac{5}{2x^5} - \frac{105}{16x^7} - \frac{155}{8x^9} - \frac{1965}{32x^{11}} - \frac{3265}{16x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 4x^2 - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{x^2}{4} - 1\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{4} - 1 - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 1\right) &&= -\frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 1\right) &&= \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 4x^2 - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + (-)\left(\frac{x}{2}\right) \\
&= \frac{1}{2x} - \frac{x}{2} \\
&= \frac{1}{2x} - \frac{x}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{1}{2x} - \frac{x}{2}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{2}\right) + \left(\frac{1}{2x} - \frac{x}{2}\right)^2 - \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{x}{2}\right) dx} \\
&= \sqrt{x}\, \mathrm{e}^{-\frac{x^2}{4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x^3 - x}{x^2} \, dx} \\
&= z_1 e^{-\frac{x^2}{4} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\, \mathrm{e}^{-\frac{x^2}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-\frac{x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^3-x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{2}+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\right) + c_2\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.139.2 Maple step by step solution

Let's solve
$x^2\left(\frac{d}{dx}y'\right) - x(-x^2+1)\,y' + (x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ◦ Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
  - ◦ Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$
  - ◦ Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

    Rewrite ODE with series expansions

$$a_0(-1+r)^2 x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-2}(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 1$
- Each term must be 0
  $a_1 r^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\,(a_k(k+r-1) + a_{k-2}) = 0$
- Shift index using $k- >k+2$
  $(k+r+1)\,(a_{k+2}(k+r+1) + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k}{k+r+1}$
- Recursion relation for $r = 1$
  $a_{k+2} = -\frac{a_k}{k+2}$
- Solution for $r = 1$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{k+2}, a_1 = 0\right]$

1.140 problem 142

Internal problem ID [8278]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 142
Date solved : `Monday, October 21, 2024 at 05:05:05 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+1\right)y''-3x\left(-x^2+1\right)y'+4y=0$$

1.140.1 Solved as second order ode using Kovacic algorithm

Time used: 0.412 (sec)

Writing the ode as

$$\left(x^4+x^2\right)y''+\left(3x^3-3x\right)y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^4+x^2\\ B&=3x^3-3x\\ C&=4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^4 - 10x^2 - 1}{4\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3x^4 - 10x^2 - 1$$
$$t = 4\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^4 - 10x^2 - 1}{4\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 264: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 6 - 4 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} + \frac{i}{4x-4i} - \frac{i}{4(x+i)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^4 - 10x^2 - 1}{4\left(x^3 + x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^4 - 10x^2 - 1}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} + (-)(0) \\
&= \frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} \\
&= \frac{1}{2x} - \frac{x}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{2(x-i)^2} + \frac{1}{2(x+i)^2}\right) + \left(\frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)}\right)dx} \\
&= \frac{\sqrt{x}}{\sqrt{x^2+1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^3-3x}{x^4+x^2}\,dx} \\
&= z_1 e^{\frac{3\ln(x)}{2}-\frac{3\ln\left(x^2+1\right)}{2}} \\
&= z_1\left(\frac{x^{3/2}}{\left(x^2+1\right)^{3/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^2}{\left(x^2+1\right)^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3-3x}{x^4+x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{3\ln(x)-3\ln\left(x^2+1\right)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\frac{x^2}{2}+\ln\left(x\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^2}{\left(x^2+1\right)^2}\right) + c_2\left(\frac{x^2}{\left(x^2+1\right)^2}\left(\frac{x^2}{2}+\ln\left(x\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.140.2 Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d}{dx}y'\right)-3x(-x^2+1)\,y'+4y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{4y}{x^2(x^2+1)}-\frac{3(x^2-1)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{3(x^2-1)y'}{x(x^2+1)}+\frac{4y}{x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{3(x^2-1)}{x(x^2+1)},P_3(x)=\frac{4}{x^2(x^2+1)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=-3$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=4$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d}{dx}y'\right)+3x(x^2-1)\,y'+4y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

  $x^m\cdot y'=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot y'=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^{m} \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $x^{m} \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_{k}(k+r)(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $x^{m} \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(-2+r)^{2} x^{r} + a_{1}(-1+r)^{2} x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_{k}(k+r-2)^{2} + a_{k-2}(k+r-2)(k+r)\right) x^{k+r}\right) = 0$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^{2} = 0$
- Values of r that satisfy the indicial equation

  $r = 2$
- Each term must be 0

  $a_{1}(-1+r)^{2} = 0$
- Solve for the dependent coefficient(s)

  $a_{1} = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)\left(a_{k}(k+r-2) + a_{k-2}(k+r)\right) = 0$
- Shift index using $k->k+2$

  $(k+r)\left(a_{k+2}(k+r) + a_{k}(k+r+2)\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_{k}(k+r+2)}{k+r}$
- Recursion relation for $r = 2$

  $a_{k+2} = -\frac{a_{k}(k+4)}{k+2}$
- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_{k} x^{k+2}, a_{k+2} = -\frac{a_{k}(k+4)}{k+2}, a_{1} = 0\right]$

1.141 problem 143

Internal problem ID [8279]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 143
Date solved : `Monday, October 21, 2024 at 05:05:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + 2x^3y' + \left(3x^2+1\right)y = 0$$

1.141.1 Solved as second order ode using Kovacic algorithm

Time used: 0.300 (sec)

Writing the ode as

$$4x^2y'' + 2x^3y' + \left(3x^2+1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= 2x^3 \\ C &= 3x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 8x^2 - 4}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^4 - 8x^2 - 4$$
$$t = 16x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 8x^2 - 4}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 266: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{16} - \frac{1}{2} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} - \frac{1}{x} - \frac{5}{2x^3} - \frac{10}{x^5} - \frac{105}{2x^7} - \frac{310}{x^9} - \frac{1965}{x^{11}} - \frac{13060}{x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= \frac{x}{4}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4 - 8x^2 - 4}{16x^2} \\
&= Q + \frac{R}{16x^2} \\
&= \left(\frac{x^2}{16} - \frac{1}{2}\right) + \left(-\frac{1}{4x^2}\right) \\
&= \frac{x^2}{16} - \frac{1}{2} - \frac{1}{4x^2}
\end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{1}{2}\right) - (0) \\
&= -\frac{1}{2}
\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{4} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{4}} - 1\right) &&= -\frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{4}} - 1\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 8x^2 - 4}{16x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{4}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{1}{2x} + (-)\left(\frac{x}{4}\right) \\ &= \frac{1}{2x} - \frac{x}{4} \\ &= \frac{1}{2x} - \frac{x}{4}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(\frac{1}{2x} - \frac{x}{4}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{4}\right) + \left(\frac{1}{2x} - \frac{x}{4}\right)^2 - \left(\frac{x^4 - 8x^2 - 4}{16x^2}\right)\right) &= 0 \\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{x}{4}\right) dx} \\ &= \sqrt{x}\, e^{-\frac{x^2}{8}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^3}{4x^2} \, dx} \\ &= z_1 e^{-\frac{x^2}{8}} \\ &= z_1 \left(e^{-\frac{x^2}{8}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{4}} \sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3}{4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{4}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{4}\right)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-\frac{x^2}{4}} \sqrt{x}\right) + c_2 \left(\mathrm{e}^{-\frac{x^2}{4}} \sqrt{x} \left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{4}\right)}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.141.2 Maple step by step solution

Let's solve

$4x^2 \left(\frac{d}{dx} y'\right) + 2x^3 y' + (3x^2 + 1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx} y'$

- Isolate 2nd derivative

  $\frac{d}{dx} y' = -\frac{(3x^2+1)y}{4x^2} - \frac{y'x}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y' + \frac{y'x}{2} + \frac{(3x^2+1)y}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{x}{2}, P_3(x) = \frac{3x^2+1}{4x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 0$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = \frac{1}{4}$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d}{dx}y'\right) + 2x^3y' + (3x^2+1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ◦ Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ◦ Convert $x^3 \cdot y'$ to series expansion

  $x^3 \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r+2}$

- ◦ Shift index using $k- >k-2$

  $x^3 \cdot y' = \sum_{k=2}^{\infty} a_{k-2}(k-2+r)\,x^{k+r}$

- ◦ Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+2r)^2 x^r + a_1(1+2r)^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r-1)^2 + a_{k-2}(2k+2r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+2r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = \frac{1}{2}$
- Each term must be 0
  $a_1(1+2r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_k(2k+2r-1)^2 + a_{k-2}(2k+2r-1) = 0$
- Shift index using $k->k+2$
  $a_{k+2}(2k+2r+3)^2 + a_k(2k+2r+3) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k}{2k+2r+3}$
- Recursion relation for $r = \frac{1}{2}$
  $a_{k+2} = -\frac{a_k}{2k+4}$
- Solution for $r = \frac{1}{2}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k}{2k+4}, a_1 = 0\right]$

1.142 problem 144

Internal problem ID [8280]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 144
Date solved : `Monday, October 21, 2024 at 05:05:07 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2+1)\,y''-x(-2x^2+1)\,y'+y=0$$

1.142.1 Solved as second order ode using Kovacic algorithm

Time used: 0.300 (sec)

Writing the ode as

$$(x^4+x^2)\,y''+(2x^3-x)\,y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= 2x^3-x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2x^2 - 1}{4\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2x^2 - 1 \\ t &= 4\left(x^3 + x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2x^2 - 1}{4\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 268: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} - \frac{3}{16(x-i)^2} - \frac{3}{16(x+i)^2} - \frac{5i}{16(x-i)} + \frac{5i}{16(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{2x^2 - 1}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-i$	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x - c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{1}{4x - 4i} + \frac{1}{4x + 4i} + (-)(0) \\
&= \frac{1}{2x} + \frac{1}{4x - 4i} + \frac{1}{4x + 4i} \\
&= \frac{1}{2x} + \frac{x}{2x^2 + 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{1}{4x - 4i} + \frac{1}{4x + 4i}\right)(0) + \Bigg(\left(-\frac{1}{2x^2} - \frac{1}{4(x - i)^2} - \frac{1}{4(x + i)^2}\right) + \Bigg(\frac{1}{2x} + \frac{1}{4x - 4i} + \frac{1}{4x +$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2x} + \frac{1}{4x - 4i} + \frac{1}{4x + 4i}\right) dx} \\
&= \left(x^2 + 1\right)^{1/4} \sqrt{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3-x}{x^4+x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln\left(x^2+1\right)}{4}+\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\sqrt{x}}{\left(x^2+1\right)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x}{\sqrt{x^2+1}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3-x}{x^4+x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln\left(x^2+1\right)}{2}+\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(-\operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x}{\sqrt{x^2+1}}\right) + c_2 \left(\frac{x}{\sqrt{x^2+1}}\left(-\operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.142.2 Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d}{dx}y'\right)-x(-2x^2+1)\,y'+y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{y}{x^2(x^2+1)}-\frac{(2x^2-1)\,y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(2x^2-1)\,y'}{x(x^2+1)}+\frac{y}{x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{2x^2-1}{x(x^2+1)},P_3(x)=\frac{1}{x^2(x^2+1)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=1$

- ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d}{dx}y'\right)+x(2x^2-1)\,y'+y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

  $x^m\cdot y'=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $x^m\cdot y'=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

  $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+r)^2\,x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-2}(k-2+r)\,(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+r)^2 = 0$$

- Values of r that satisfy the indicial equation

  $$r = 1$$

- Each term must be 0

  $$a_1 r^2 = 0$$

- Solve for the dependent coefficient(s)

  $$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$(k+r-1)\,(a_k(k+r-1) + a_{k-2}(k-2+r)) = 0$$

- Shift index using $k- > k+2$

  $$(k+r+1)\,(a_{k+2}(k+r+1) + a_k(k+r)) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = -\frac{a_k(k+r)}{k+r+1}$$

- Recursion relation for $r = 1$

  $$a_{k+2} = -\frac{a_k(k+1)}{k+2}$$

- Solution for $r = 1$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k(k+1)}{k+2}, a_1 = 0\right]$$

1.143 problem 145

Internal problem ID [8281]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 145
Date solved : `Monday, October 21, 2024 at 05:05:08 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(x^2+2\right)y''+7x^3y'+\left(3x^2+1\right)y=0$$

1.143.1 Solved as second order ode using Kovacic algorithm

Time used: 0.380 (sec)

Writing the ode as

$$\left(2x^4+4x^2\right)y''+7x^3y'+\left(3x^2+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+4x^2 \\ B &= 7x^3 \\ C &= 3x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3x^4 - 16}{16(x^3 + 2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -3x^4 - 16$$
$$t = 16(x^3 + 2x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3x^4 - 16}{16(x^3 + 2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 270: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 6 - 4 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{1}{4x^2} - \frac{7}{64\left(x - i\sqrt{2}\right)^2} - \frac{7}{64\left(x + i\sqrt{2}\right)^2} - \frac{9i\sqrt{2}}{128\left(x - i\sqrt{2}\right)} + \frac{9i\sqrt{2}}{128\left(x + i\sqrt{2}\right)}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}
$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{8}
\end{aligned}
$$

For the pole at $x=-i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{7}{8} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-3x^4-16}{16\left(x^3+2x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-3x^4-16}{16\left(x^3+2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$i\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$-i\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= \frac{3}{4} - \left(\frac{3}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}} + (0) \\ &= \frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}} \\ &= \frac{1}{2x} + \frac{x}{4x^2 + 8} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{8\left(x - i\sqrt{2}\right)^2} - \frac{1}{8\left(x + i\sqrt{2}\right)^2}\right) + \left(\frac{1}{2x} + \frac{}{8x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}}\right) dx} \\ &= \left(x^2 + 2\right)^{1/8} \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^3}{2x^4+4x^2}\,dx} \\
&= z_1 e^{-\frac{7\ln\left(x^2+2\right)}{8}} \\
&= z_1\left(\frac{1}{\left(x^2+2\right)^{7/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\sqrt{x}}{\left(x^2+2\right)^{3/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^3}{2x^4+4x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{7\ln\left(x^2+2\right)}{4}}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\int \frac{1}{\left(x^2+2\right)^{1/4} x}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\sqrt{x}}{\left(x^2+2\right)^{3/4}}\right) + c_2\left(\frac{\sqrt{x}}{\left(x^2+2\right)^{3/4}}\left(\int \frac{1}{\left(x^2+2\right)^{1/4} x}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.143.2 Maple step by step solution

Let's solve

$2x^2(x^2+2)\left(\frac{d}{dx}y'\right)+7x^3y'+(3x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{(3x^2+1)y}{2x^2(x^2+2)}-\frac{7xy'}{2(x^2+2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{7xy'}{2(x^2+2)}+\frac{(3x^2+1)y}{2x^2(x^2+2)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{7x}{2(x^2+2)},P_3(x)=\frac{3x^2+1}{2x^2(x^2+2)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$\left(x\cdot P_2(x)\right)\Big|_{x=0}=0$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=\frac{1}{4}$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$2x^2(x^2+2)\left(\frac{d}{dx}y'\right)+7x^3y'+(3x^2+1)\,y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

$x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

$x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^3\cdot y'$ to series expansion

$$x^3 \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r+2}$$

- Shift index using $k- >k-2$

$$x^3 \cdot y' = \sum_{k=2}^{\infty} a_{k-2}(k-2+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+2r)^2\, x^r + a_1(1+2r)^2\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r-1)^2 + a_{k-2}(2k+2r-1)\,(k+r-1)\right) x\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(-1+2r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = \frac{1}{2}$$

- Each term must be 0

$$a_1(1+2r)^2 = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$4\left(\frac{a_{k-2}(k+r-1)}{2} + a_k\left(k+r-\frac{1}{2}\right)\right)\left(k+r-\frac{1}{2}\right) = 0$$

- Shift index using $k- >k+2$

$$4\left(\frac{a_k(k+r+1)}{2} + a_{k+2}\left(k+\frac{3}{2}+r\right)\right)\left(k+\frac{3}{2}+r\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k(k+r+1)}{2k+2r+3}$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+4}$$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+4}, a_1 = 0\right]$$

1.144 problem 146

Internal problem ID [8282]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 146
Date solved : `Monday, October 21, 2024 at 05:05:10 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2+1)\,y''-x(-4x^2+1)\,y'+(2x^2+1)\,y=0$$

1.144.1 Solved as second order ode using Kovacic algorithm

Time used: 0.333 (sec)

Writing the ode as

$$(x^4+x^2)\,y''+(4x^3-x)\,y'+(2x^2+1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^4+x^2\\B&=4x^3-x\\C&=2x^2+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-6x^2 - 1}{4\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -6x^2 - 1$$
$$t = 4\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-6x^2 - 1}{4\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 272: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 6 - 2 \\
&= 4
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{1}{4x^2} + \frac{5}{16\,(x-i)^2} + \frac{5}{16\,(x+i)^2} + \frac{3i}{16\,(x-i)} - \frac{3i}{16\,(x+i)}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-6x^2 - 1}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-i$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(x+i)} + (0) \\
&= \frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(x+i)} \\
&= \frac{1}{2x^3 + 2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(x+i)} \right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{4(x-i)^2} + \frac{1}{4(x+i)^2} \right) + \left(\frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(x+i)} \right) dx} \\
&= \frac{\sqrt{x}}{(x^2+1)^{1/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x^3-x}{x^4+x^2}\, dx} \\
&= z_1 e^{\frac{\ln(x)}{2}-\frac{5\ln(x^2+1)}{4}} \\
&= z_1 \left(\frac{\sqrt{x}}{(x^2+1)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x}{(x^2+1)^{3/2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x^3-x}{x^4+x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(x)-\frac{5\ln(x^2+1)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\sqrt{x^2+1} - \operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x}{(x^2+1)^{3/2}}\right) + c_2 \left(\frac{x}{(x^2+1)^{3/2}} \left(\sqrt{x^2+1} - \operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.144.2 Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d}{dx}y'\right)-x(-4x^2+1)\,y'+(2x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(2x^2+1)y}{x^2(x^2+1)}-\frac{(4x^2-1)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(4x^2-1)y'}{x(x^2+1)}+\frac{(2x^2+1)y}{x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{4x^2-1}{x(x^2+1)},P_3(x)=\frac{2x^2+1}{x^2(x^2+1)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-1$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=1$

  ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d}{dx}y'\right)+x(4x^2-1)\,y'+(2x^2+1)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

    $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

    $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)^2\, x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-2}(k+r)\,(k+r-1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 1$
- Each term must be 0

  $a_1 r^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\,(a_k(k+r-1) + a_{k-2}(k+r)) = 0$
- Shift index using $k->k+2$

  $(k+r+1)\,(a_{k+2}(k+r+1) + a_k(k+r+2)) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+2)}{k+r+1}$
- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k(k+3)}{k+2}$
- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k(k+3)}{k+2}, a_1 = 0\right]$

1.145 problem 147

Internal problem ID [8283]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 147
Date solved : `Monday, October 21, 2024 at 05:05:11 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+4\right)y''+3x\left(3x^2+8\right)y'+\left(-9x^2+1\right)y=0$$

1.145.1 Solved as second order ode using Kovacic algorithm

Time used: 0.460 (sec)

Writing the ode as

$$\left(4x^4+16x^2\right)y''+\left(9x^3+24x\right)y'+\left(-9x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+16x^2 \\ B &= 9x^3+24x \\ C &= -9x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{153x^4 + 704x^2 - 256}{64\,(x^3 + 4x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 153x^4 + 704x^2 - 256$$
$$t = 64(x^3 + 4x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{153x^4 + 704x^2 - 256}{64\,(x^3 + 4x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 274: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(x^3 + 4x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 2i$ of order 2. There is a pole at $x = -2i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{39}{256(x-2i)^2} - \frac{39}{256(x+2i)^2} - \frac{377i}{512(x-2i)} + \frac{377i}{512(x+2i)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 2i$ let b be the coefficient of $\frac{1}{(x-2i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{39}{256}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{16} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{16} \end{aligned}$$

For the pole at $x=-2i$ let b be the coefficient of $\frac{1}{(x+2i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{39}{256}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{13}{16} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{3}{16}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{153x^4+704x^2-256}{64\left(x^3+4x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{153}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{17}{8} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{9}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{153x^4+704x^2-256}{64\left(x^3+4x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$2i$	2	0	$\frac{13}{16}$	$\frac{3}{16}$
$-2i$	2	0	$\frac{13}{16}$	$\frac{3}{16}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{17}{8}$	$-\frac{9}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{17}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+ + \alpha_{c_3}^+\right)\\
&= \frac{17}{8} - \left(\frac{17}{8}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x-c_3}\right) + (+)[\sqrt{r}]_\infty\\
&= \frac{1}{2x} + \frac{13}{16\,(x-2i)} + \frac{13}{16\,(x+2i)} + (0)\\
&= \frac{1}{2x} + \frac{13}{16\,(x-2i)} + \frac{13}{16\,(x+2i)}\\
&= \frac{1}{2x} + \frac{13x}{8x^2+32}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} + \frac{13}{16\,(x-2i)} + \frac{13}{16\,(x+2i)}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{13}{16\,(x-2i)^2} - \frac{13}{16\,(x+2i)^2}\right) + \left(\frac{1}{2x} + \frac{1}{16\,(x
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\,dx}\\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{13}{16(x-2i)} + \frac{13}{16(x+2i)}\right)dx}\\
&= \left(x^2+4\right)^{13/16}\sqrt{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{9x^3+24x}{4x^4+16x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln\left(x^2+4\right)}{16}-\frac{3\ln(x)}{4}} \\
&= z_1\left(\frac{1}{\left(x^2+4\right)^{3/16} x^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(x^2+4\right)^{5/8}}{x^{1/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{9x^3+24x}{4x^4+16x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln\left(x^2+4\right)}{8}-\frac{3\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{3\ln\left(x^2+4\right)}{8}-\frac{3\ln(x)}{2}}\sqrt{x}}{\left(x^2+4\right)^{5/4}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\left(x^2+4\right)^{5/8}}{x^{1/4}}\right) + c_2\left(\frac{\left(x^2+4\right)^{5/8}}{x^{1/4}}\left(\int \frac{\mathrm{e}^{-\frac{3\ln\left(x^2+4\right)}{8}-\frac{3\ln(x)}{2}}\sqrt{x}}{\left(x^2+4\right)^{5/4}}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.145.2 Maple step by step solution

Let's solve

$4x^2(x^2+4)\left(\frac{d}{dx}y'\right)+3x(3x^2+8)\,y'+(-9x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+4r)^2 x^r + a_1(5+4r)^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(4k+4r+1)^2 + a_{k-2}(4k+4r+1)\,(k-3+r)\right) x^{k+}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(1+4r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = -\frac{1}{4}$$

- Each term must be 0

$$a_1(5+4r)^2 = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$16\left(k+r+\frac{1}{4}\right)\left(\frac{a_{k-2}(k-3+r)}{4} + a_k\left(k+r+\frac{1}{4}\right)\right) = 0$$

- Shift index using $k- >k+2$

$$16\left(k+\frac{9}{4}+r\right)\left(\frac{a_k(k+r-1)}{4} + a_{k+2}\left(k+\frac{9}{4}+r\right)\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k(k+r-1)}{4k+4r+9}$$

- Recursion relation for $r = -\frac{1}{4}$

$$a_{k+2} = -\frac{a_k\left(k-\frac{5}{4}\right)}{4k+8}$$

- Solution for $r = -\frac{1}{4}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{4}}, a_{k+2} = -\frac{a_k\left(k-\frac{5}{4}\right)}{4k+8}, a_1 = 0\right]$$

1.146 problem 148

Internal problem ID [8284]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 148
Date solved : `Monday, October 21, 2024 at 05:05:13 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2\left(x^2+3\right)y''+x\left(11x^2+3\right)y'+\left(5x^2+1\right)y=0$$

1.146.1 Solved as second order ode using Kovacic algorithm

Time used: 0.382 (sec)

Writing the ode as

$$\left(3x^4+9x^2\right)y''+\left(11x^3+3x\right)y'+\left(5x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^4+9x^2 \\ B &= 11x^3+3x \\ C &= 5x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5x^4 + 18x^2 - 81}{36\left(x^3 + 3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -5x^4 + 18x^2 - 81$$
$$t = 36\left(x^3 + 3x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-5x^4 + 18x^2 - 81}{36\left(x^3 + 3x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 276: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^3 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{3}$ of order 2. There is a pole at $x = -i\sqrt{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} - \frac{5}{36\left(x - i\sqrt{3}\right)^2} - \frac{5}{36\left(x + i\sqrt{3}\right)^2} - \frac{7i\sqrt{3}}{108\left(x - i\sqrt{3}\right)} + \frac{7i\sqrt{3}}{108\left(x + i\sqrt{3}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

For the pole at $x = i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}\end{aligned}$$

For the pole at $x = -i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-5x^4 + 18x^2 - 81}{36\left(x^3 + 3x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{5}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-5x^4 + 18x^2 - 81}{36\left(x^3 + 3x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$i\sqrt{3}$	2	0	$\frac{5}{6}$	$\frac{1}{6}$
$-i\sqrt{3}$	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = \frac{5}{6}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{-} + \alpha_{c_3}^{-}\right)\\
&= \frac{5}{6} - \left(\frac{5}{6}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (+)[\sqrt{r}]_\infty\\
&= \frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}} + (0)\\
&= \frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}}\\
&= \frac{1}{2x} + \frac{x}{3x^2+9}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{6\left(x-i\sqrt{3}\right)^2} - \frac{1}{6\left(x+i\sqrt{3}\right)^2}\right) + \left(\frac{1}{2x} + \frac{}{6x}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx}\\
&= e^{\int \left(\frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}}\right)dx}\\
&= \left(x^2+3\right)^{1/6}\sqrt{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{11x^3+3x}{3x^4+9x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{6}-\frac{5\ln\left(x^2+3\right)}{6}} \\
&= z_1\left(\frac{1}{x^{1/6}\left(x^2+3\right)^{5/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{\left(x^2+3\right)^{2/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{11x^3+3x}{3x^4+9x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{3}-\frac{5\ln\left(x^2+3\right)}{3}}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{3}-\frac{5\ln\left(x^2+3\right)}{3}}\left(x^2+3\right)^{4/3}}{x^{2/3}}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/3}}{\left(x^2+3\right)^{2/3}}\right) + c_2\left(\frac{x^{1/3}}{\left(x^2+3\right)^{2/3}}\left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{3}-\frac{5\ln\left(x^2+3\right)}{3}}\left(x^2+3\right)^{4/3}}{x^{2/3}}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.146.2 Maple step by step solution

Let's solve

$3x^2(x^2+3)\left(\frac{d}{dx}y'\right)+x(11x^2+3)\,y'+(5x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=-\frac{(5x^2+1)y}{3x^2(x^2+3)}-\frac{(11x^2+3)y'}{3x(x^2+3)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'+\frac{(11x^2+3)y'}{3x(x^2+3)}+\frac{(5x^2+1)y}{3x^2(x^2+3)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{11x^2+3}{3x(x^2+3)},P_3(x)=\frac{5x^2+1}{3x^2(x^2+3)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{1}{3}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=\frac{1}{9}$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $3x^2(x^2+3)\left(\frac{d}{dx}y'\right)+x(11x^2+3)\,y'+(5x^2+1)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+3r)^2\, x^r + a_1(2+3r)^2\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-1)^2 + a_{k-2}(3k+3r-1)\,(k+r-1)\right) x\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(-1+3r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = \frac{1}{3}$$

- Each term must be 0

$$a_1(2+3r)^2 = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$9\left(\frac{a_{k-2}(k+r-1)}{3} + a_k\left(k+r-\frac{1}{3}\right)\right)\left(k+r-\frac{1}{3}\right) = 0$$

- Shift index using $k->k+2$

$$9\left(\frac{a_k(k+r+1)}{3} + a_{k+2}\left(k+\frac{5}{3}+r\right)\right)\left(k+\frac{5}{3}+r\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k(k+r+1)}{3k+3r+5}$$

- Recursion relation for $r = \frac{1}{3}$

$$a_{k+2} = -\frac{a_k\left(k+\frac{4}{3}\right)}{3k+6}$$

- Solution for $r = \frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{a_k\left(k+\frac{4}{3}\right)}{3k+6}, a_1 = 0\right]$$

1.147 problem 149

Internal problem ID [8285]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 149
Date solved : `Monday, October 21, 2024 at 05:05:14 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2y'' - 3x\left(-2x^2+7\right)y' + \left(2x^2+25\right)y = 0$$

1.147.1 Solved as second order ode using Kovacic algorithm

Time used: 0.339 (sec)

Writing the ode as

$$9x^2y'' + \left(6x^3 - 21x\right)y' + \left(2x^2+25\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= 6x^3 - 21x \\ C &= 2x^2 + 25 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 - 24x^2 - 9}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4x^4 - 24x^2 - 9$$
$$t = 36x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 - 24x^2 - 9}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 278: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{9} - \frac{2}{3} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{3} - \frac{1}{x} - \frac{15}{8x^3} - \frac{45}{8x^5} - \frac{2835}{128x^7} - \frac{12555}{128x^9} - \frac{477495}{1024x^{11}} - \frac{2380185}{1024x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{3}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{3} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{9}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 - 24x^2 - 9}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{x^2}{9} - \frac{2}{3}\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{9} - \frac{2}{3} - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{2}{3}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{2}{3}\right) - (0) \\ &= -\frac{2}{3} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{3} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= -\frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^4 - 24x^2 - 9}{36x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{3}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + (-)\left(\frac{x}{3}\right) \\
&= \frac{1}{2x} - \frac{x}{3} \\
&= \frac{1}{2x} - \frac{x}{3}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} - \frac{x}{3}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{3}\right) + \left(\frac{1}{2x} - \frac{x}{3}\right)^2 - \left(\frac{4x^4 - 24x^2 - 9}{36x^2}\right)\right) = 0
$$

$$
0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2x} - \frac{x}{3}\right) dx} \\
&= \sqrt{x}\, e^{-\frac{x^2}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{6x^3 - 21x}{9x^2} \, dx} \\
&= z_1 e^{-\frac{x^2}{6} + \frac{7 \ln(x)}{6}} \\
&= z_1 \left(x^{7/6} e^{-\frac{x^2}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = x^{5/3}\mathrm{e}^{-\frac{x^2}{3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6x^3-21x}{9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{3}+\frac{7\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{3}\right)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{5/3}\mathrm{e}^{-\frac{x^2}{3}}\right) + c_2 \left(x^{5/3}\mathrm{e}^{-\frac{x^2}{3}}\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{3}\right)}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.147.2 Maple step by step solution

Let's solve

$9x^2\left(\frac{d}{dx}y'\right) - 3x(-2x^2+7)\,y' + (2x^2+25)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(2x^2+25)y}{9x^2} - \frac{(2x^2-7)y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y' + \frac{(2x^2-7)y'}{3x} + \frac{(2x^2+25)y}{9x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{2x^2-7}{3x}, P_3(x) = \frac{2x^2+25}{9x^2}\right]$
- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = -\frac{7}{3}$
- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{25}{9}$
- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $9x^2\left(\frac{d}{dx}y'\right) + 3x(2x^2-7)\,y' + (2x^2+25)\,y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- ○ Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
- ○ Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- ○ Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-5+3r)^2 x^r + a_1(-2+3r)^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-5)^2 + 2a_{k-2}(3k+3r-5)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-5+3r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = \frac{5}{3}$
- Each term must be 0
  $a_1(-2+3r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_k(3k+3r-5)^2 + 2a_{k-2}(3k+3r-5) = 0$
- Shift index using $k- > k+2$
  $a_{k+2}(3k+3r+1)^2 + 2a_k(3k+3r+1) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{2a_k}{3k+3r+1}$
- Recursion relation for $r = \frac{5}{3}$
  $a_{k+2} = -\frac{2a_k}{3k+6}$
- Solution for $r = \frac{5}{3}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{5}{3}}, a_{k+2} = -\frac{2a_k}{3k+6}, a_1 = 0\right]$

1.148 problem 150

Internal problem ID [8286]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 150
Date solved : `Monday, October 21, 2024 at 05:05:15 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x\left(-x^2+1\right)y' + \left(x^2+1\right)y = 0$$

1.148.1 Solved as second order ode using Kovacic algorithm

Time used: 0.304 (sec)

Writing the ode as

$$x^2y'' + \left(x^3-x\right)y' + \left(x^2+1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^3 - x \\ C &= x^2 + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 4x^2 - 1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^4 - 4x^2 - 1$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 280: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 4 \\
&= -2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{4} - 1 - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{1}{x} - \frac{5}{4x^3} - \frac{5}{2x^5} - \frac{105}{16x^7} - \frac{155}{8x^9} - \frac{1965}{32x^{11}} - \frac{3265}{16x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 4x^2 - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{x^2}{4} - 1\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{4} - 1 - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 1\right) &&= -\frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 1\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 4x^2 - 1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + (-)\left(\frac{x}{2}\right) \\
&= \frac{1}{2x} - \frac{x}{2} \\
&= \frac{1}{2x} - \frac{x}{2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2x} - \frac{x}{2}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{2}\right) + \left(\frac{1}{2x} - \frac{x}{2}\right)^2 - \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{x}{2}\right) dx} \\
&= \sqrt{x}\,\mathrm{e}^{-\frac{x^2}{4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^3 - x}{x^2}\, dx} \\
&= z_1 e^{-\frac{x^2}{4} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\,\mathrm{e}^{-\frac{x^2}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-\frac{x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^3-x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}+\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\right) + c_2\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.148.2 Maple step by step solution

Let's solve

$x^2\left(\frac{d}{dx}y'\right) - x(-x^2+1)\,y' + (x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(x^2+1)y}{x^2} - \frac{(x^2-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y' + \frac{(x^2-1)y'}{x} + \frac{(x^2+1)y}{x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{x^2-1}{x}, P_3(x) = \frac{x^2+1}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -1$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 1$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $x^2\left(\frac{d}{dx}y'\right) + x(x^2-1)\,y' + (x^2+1)\,y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

    Rewrite ODE with series expansions

$$a_0(-1+r)^2 x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k (k+r-1)^2 + a_{k-2}(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 1$
- Each term must be 0
  $a_1 r^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_k(k+r-1) + a_{k-2}\right) = 0$
- Shift index using $k- >k+2$
  $(k+r+1)\left(a_{k+2}(k+r+1) + a_k\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k}{k+r+1}$
- Recursion relation for $r = 1$
  $a_{k+2} = -\frac{a_k}{k+2}$
- Solution for $r = 1$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{k+2}, a_1 = 0\right]$

1.149 problem 151

Internal problem ID [8287]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 151
Date solved : `Monday, October 21, 2024 at 05:05:16 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''+3xy'+(1+4x)\,y=0$$

1.149.1 Solved as second order ode using Kovacic algorithm

Time used: 0.276 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+3xy'+(1+4x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -2x^3+x^2\\ B &= 3x \\ C &= 1+4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{32x^2 + 16x - 1}{4(2x^2 - x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 32x^2 + 16x - 1 \\ t &= 4(2x^2 - x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{32x^2 + 16x - 1}{4(2x^2 - x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 282: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{x} - \frac{1}{4x^2} + \frac{15}{4\left(x - \frac{1}{2}\right)^2} - \frac{3}{x - \frac{1}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading

coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{32x^2 + 16x - 1}{4\left(2x^2 - x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{32x^2 + 16x - 1}{4\left(2x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{1}{2x} - \frac{3}{2\left(x-\frac{1}{2}\right)} + (-)\,(0) \\ &= \frac{1}{2x} - \frac{3}{2\left(x-\frac{1}{2}\right)} \\ &= \frac{-1-4x}{4x^2-2x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{3}{2\left(x-\frac{1}{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{3}{2\left(x-\frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{3}{2\left(x-\frac{1}{2}\right)}\right)^2 - \left(\frac{32x^2+16x-1}{4\left(2x^2-x\right)^2}\right)\right)$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{3}{2\left(x-\frac{1}{2}\right)}\right) dx} \\ &= \frac{\sqrt{x}}{(-1+2x)^{3/2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3x}{-2x^3+x^2}\, dx} \\ &= z_1 e^{-\frac{3\ln(x)}{2} + \frac{3\ln(-1+2x)}{2}} \\ &= z_1 \left(\frac{(-1+2x)^{3/2}}{x^{3/2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{-2x^3+x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-3\ln(x)+3\ln(-1+2x)}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{8x^3}{3} + \frac{1}{2} + 6x - 6x^2 - \ln\left(x\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\frac{8x^3}{3} + \frac{1}{2} + 6x - 6x^2 - \ln\left(x\right)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.149.2 Maple step by step solution

Let's solve

$x^2(1-2x)\left(\frac{d}{dx}y'\right) + 3xy' + (1+4x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(1+4x)y}{x^2(-1+2x)} + \frac{3y'}{x(-1+2x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{3y'}{x(-1+2x)} - \frac{(1+4x)y}{x^2(-1+2x)} = 0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x) = -\frac{3}{x(-1+2x)}, P_3(x) = -\frac{1+4x}{x^2(-1+2x)}\right]$
- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 3$
- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 1$
- ○ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(-1+2x)\left(\frac{d}{dx}y'\right) - 3xy' + (-1-4x)\,y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- ○ Shift index using $k- > k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- ○ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$
- ○ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$
- ○ Shift index using $k- > k+2-m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(1+r)^2\, x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r+1)^2 + 2a_{k-1}(k+r)\,(k-3+r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-(1+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = -1$
- Each term in the series must be 0, giving the recursion relation
  $-a_k(k+r+1)^2 + 2a_{k-1}(k+r)(k-3+r) = 0$
- Shift index using $k->k+1$
  $-a_{k+1}(k+2+r)^2 + 2a_k(k+r+1)(k+r-2) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{2a_k(k+r+1)(k+r-2)}{(k+2+r)^2}$
- Recursion relation for $r = -1$; series terminates at $k = 3$
  $a_{k+1} = \frac{2a_k k(k-3)}{(k+1)^2}$
- Apply recursion relation for $k = 0$
  $a_1 = 0$
- Apply recursion relation for $k = 1$
  $a_2 = -a_1$
- Express in terms of a_0
  $a_2 = 0$
- Apply recursion relation for $k = 2$
  $a_3 = -\frac{4a_2}{9}$
- Express in terms of a_0
  $a_3 = 0$
- Terminating series solution of the ODE for $r = -1$. Use reduction of order to find the second
  $y = a_0 \cdot 0$

1.150 problem 152

Internal problem ID [8288]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 152
Date solved : `Monday, October 21, 2024 at 05:05:17 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x(1+x)\,y''+(1-x)\,y'+y=0$$

1.150.1 Solved as second order ode using Kovacic algorithm

Time used: 0.275 (sec)

Writing the ode as

$$\left(x^2+x\right)y''+(1-x)\,y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2+x\\ B&=1-x\\ C&=1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-x^2 - 10x - 1}{4\left(x^2 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -x^2 - 10x - 1 \\
t &= 4\left(x^2 + x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-x^2 - 10x - 1}{4\left(x^2 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 284: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{2}{1+x} + \frac{2}{(1+x)^2} - \frac{2}{x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 10x - 1}{4(x^2 + x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{-x^2-10x-1}{4\left(x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-1	2	0	2	-1
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right) \\
&= \frac{1}{2}-\left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{1+x} + \frac{1}{2x} + (-)(0) \\
&= -\frac{1}{1+x} + \frac{1}{2x} \\
&= -\frac{x-1}{2x(1+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{1+x} + \frac{1}{2x}\right)(1) + \left(\left(\frac{1}{(1+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{1}{1+x} + \frac{1}{2x}\right)^2 - \left(\frac{-x^2 - 10x - 1}{4(x^2 + x)^2}\right)\right) = 0
$$

$$
\frac{1 + a_0}{x(1+x)} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = -1\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x - 1
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x - 1) \, e^{\int \left(-\frac{1}{1+x} + \frac{1}{2x}\right) dx} \\
&= (x - 1) \, e^{\frac{\ln(x)}{2} - \ln(1+x)} \\
&= \frac{(x - 1)\sqrt{x}}{1 + x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1-x}{x^2+x}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}+\ln(1+x)} \\
&= z_1 \left(\frac{1+x}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x - 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1-x}{x^2+x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)+2\ln(1+x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{4}{x-1} + \ln(x)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x-1) + c_2\left(x - 1\left(-\frac{4}{x-1} + \ln(x)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.150.2 Maple step by step solution

Let's solve

$x(1+x)\left(\frac{d}{dx}y'\right)+(1-x)\,y'+y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{y}{x(1+x)}+\frac{(x-1)y'}{x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'-\frac{(x-1)y'}{x(1+x)}+\frac{y}{x(1+x)}=0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

$\left[P_2(x)=-\frac{x-1}{x(1+x)}, P_3(x)=\frac{1}{x(1+x)}\right]$

- ○ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

$\left.((1+x)\cdot P_2(x))\right|_{x=-1}=-2$

- ○ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

$\left.\left((1+x)^2\cdot P_3(x)\right)\right|_{x=-1}=0$

- ○ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$x(1+x)\left(\frac{d}{dx}y'\right)+(1-x)\,y'+y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^2-u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(2-u)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0 r(-3+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)(k-2+r) + a_k(k+r-1)^2\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-r(-3+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 3\}$
- Each term in the series must be 0, giving the recursion relation
  $-a_{k+1}(k+1+r)(k-2+r) + a_k(k+r-1)^2 = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k(k+r-1)^2}{(k+1+r)(k-2+r)}$
- Recursion relation for $r = 0$; series terminates at $k = 1$
  $a_{k+1} = \frac{a_k(k-1)^2}{(k+1)(k-2)}$
- Apply recursion relation for $k = 0$
  $a_1 = -\frac{a_0}{2}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li
  $y(u) = a_0 \cdot \left(1 - \frac{u}{2}\right)$
- Revert the change of variables $u = 1 + x$
  $\left[y = a_0\left(-\frac{x}{2} + \frac{1}{2}\right)\right]$
- Recursion relation for $r = 3$
  $a_{k+1} = \frac{a_k(k+2)^2}{(k+4)(k+1)}$
- Solution for $r = 3$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+3}, a_{k+1} = \frac{a_k(k+2)^2}{(k+4)(k+1)}\right]$
- Revert the change of variables $u = 1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+3}, a_{k+1} = \frac{a_k (k+2)^2}{(k+4)(k+1)}\right]$$

- Combine solutions and rename parameters

$$\left[y = a_0\left(-\frac{x}{2}+\frac{1}{2}\right) + \left(\sum_{k=0}^{\infty} b_k (1+x)^{k+3}\right), b_{k+1} = \frac{b_k (k+2)^2}{(k+4)(k+1)}\right]$$

1.151 problem 153

Internal problem ID [8289]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 153
Date solved : `Monday, October 21, 2024 at 05:05:18 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-x)\,y''-x(3-5x)\,y'+(4-5x)\,y=0$$

1.151.1 Solved as second order ode using Kovacic algorithm

Time used: 0.281 (sec)

Writing the ode as

$$\left(-x^3+x^2\right)y''+\left(5x^2-3x\right)y'+(4-5x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=-x^3+x^2\\ B&=5x^2-3x\\ C&=4-5x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{15x^2 - 6x - 1}{4\left(x^2 - x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15x^2 - 6x - 1 \\ t &= 4\left(x^2 - x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15x^2 - 6x - 1}{4\left(x^2 - x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 286: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{(-1+x)^2} - \frac{1}{4x^2} + \frac{2}{-1+x} - \frac{2}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15x^2 - 6x - 1}{4(x^2 - x)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{5}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-\frac{3}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{15x^2-6x-1}{4\left(x^2-x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
1	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=\frac{5}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+}-\left(\alpha_{c_1}^{+}+\alpha_{c_2}^{+}\right) \\
&= \frac{5}{2}-\left(\frac{5}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + \frac{2}{-1+x} + (0) \\
&= \frac{1}{2x} + \frac{2}{-1+x} \\
&= \frac{-1+5x}{2x\left(-1+x\right)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2x} + \frac{2}{-1+x}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{2}{\left(-1+x\right)^2}\right) + \left(\frac{1}{2x} + \frac{2}{-1+x}\right)^2 - \left(\frac{15x^2 - 6x - 1}{4\left(x^2 - x\right)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{2}{-1+x}\right) dx} \\
&= \sqrt{x}\left(-1+x\right)^2
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{5x^2 - 3x}{-x^3 + x^2} \, dx} \\
&= z_1 e^{\frac{3\ln(x)}{2} + \ln(-1+x)} \\
&= z_1 \left(x^{3/2}(-1+x)\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^2(-1+x)^3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{5x^2-3x}{-x^3+x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{3\ln(x)+2\ln(-1+x)}}{(y_1)^2}\, dx \\ &= y_1 \left(\ln(x) - \frac{1}{3(-1+x)^3} - \frac{1}{-1+x} + \frac{1}{2(-1+x)^2} - \ln(-1+x)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x^2(-1+x)^3\right) \\ &\quad + c_2\left(x^2(-1+x)^3\left(\ln(x) - \frac{1}{3(-1+x)^3} - \frac{1}{-1+x} + \frac{1}{2(-1+x)^2} - \ln(-1+x)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.151.2 Maple step by step solution

Let's solve

$x^2(1-x)\left(\frac{d}{dx}y'\right) - x(3-5x)\,y' + (4-5x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(-4+5x)y}{x^2(-1+x)} + \frac{(5x-3)y'}{x(-1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y' - \frac{(5x-3)y'}{x(-1+x)} + \frac{(-4+5x)y}{x^2(-1+x)} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{5x-3}{x(-1+x)}, P_3(x) = \frac{-4+5x}{x^2(-1+x)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -3$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 4$
  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $x^2(-1+x)\left(\frac{d}{dx}y'\right) - x(5x-3)\,y' + (-4+5x)\,y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

    $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k- >k+2-m$

$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$

Rewrite ODE with series expansions

$-a_0(-2+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r-2)^2 + a_{k-1}(k+r-2)(k-6+r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(-2+r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 2$
- Each term in the series must be 0, giving the recursion relation

  $-a_k(k+r-2)^2 + a_{k-1}(k+r-2)(k-6+r) = 0$
- Shift index using $k- >k+1$

  $-a_{k+1}(k+r-1)^2 + a_k(k+r-1)(k+r-5) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r-5)}{k+r-1}$
- Recursion relation for $r = 2$; series terminates at $k = 3$

  $a_{k+1} = \frac{a_k(k-3)}{k+1}$
- Apply recursion relation for $k = 0$

  $a_1 = -3a_0$
- Apply recursion relation for $k = 1$

  $a_2 = -a_1$
- Express in terms of a_0

  $a_2 = 3a_0$
- Apply recursion relation for $k = 2$

  $a_3 = -\frac{a_2}{3}$
- Express in terms of a_0

  $a_3 = -a_0$
- Terminating series solution of the ODE for $r = 2$. Use reduction of order to find the second li

  $y = a_0 \cdot (-x^3 + 3x^2 - 3x + 1)$

1.152 problem 154

Internal problem ID [8290]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 154
Date solved : `Monday, October 21, 2024 at 05:05:19 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2 (x^2+1) y'' - x(9x^2+1) y' + (25x^2+1) y = 0$$

1.152.1 Solved as second order ode using Kovacic algorithm

Time used: 0.385 (sec)

Writing the ode as

$$(x^4+x^2) y'' + (-9x^3-x) y' + (25x^2+1) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= -9x^3-x \\ C &= 25x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^4 - 98x^2 - 1}{4\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -x^4 - 98x^2 - 1$$
$$t = 4\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^4 - 98x^2 - 1}{4\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 288: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{6}{(x-i)^2} + \frac{6}{(x+i)^2} + \frac{6i}{x-i} - \frac{6i}{x+i}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=3\\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=-2
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r=\frac{s}{t}=\frac{-x^4-98x^2-1}{4\left(x^3+x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-x^4-98x^2-1}{4\left(x^3+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	3	-2
$-i$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{1}{2} - \left(-\frac{7}{2}\right) \\
&= 4
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i} + (-)\,(0) \\
&= \frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i} \\
&= \frac{1}{2x} - \frac{4x}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(\frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i}\right)\left(4x^3 + 3x^2a_3 + 2a_2x + a_1\right) + \left(\left(-\frac{1}{2x^2} + \frac{2}{(x-i)^2} + \frac{}{(x-} \right.\right.
$$

$$
\underline{(x^2+1)\,(x^4a}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 1, a_1 = 0, a_2 = -4, a_3 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 4x^2 + 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^4 - 4x^2 + 1\right) \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i}\right) dx} \\
&= \left(x^4 - 4x^2 + 1\right) \mathrm{e}^{-2\ln(x^2+1) + \frac{\ln(x)}{2}} \\
&= \frac{\left(x^4 - 4x^2 + 1\right) \sqrt{x}}{\left(x^2+1\right)^2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-9x^3 - x}{x^4 + x^2} \, dx} \\
&= z_1 e^{\frac{\ln(x)}{2} + 2\ln(x^2+1)} \\
&= z_1 \left(\sqrt{x}\left(x^2+1\right)^2\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^5 - 4x^3 + x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-9x^3 - x}{x^4 + x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\ln(x) + 4\ln(x^2+1)}}{(y_1)^2} \, dx \\
&= y_1 \left(\ln(x) + \frac{-6x^2 + 3}{x^4 - 4x^2 + 1}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^5 - 4x^3 + x\right) + c_2\left(x^5 - 4x^3 + x\left(\ln(x) + \frac{-6x^2 + 3}{x^4 - 4x^2 + 1}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.152.2 Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d}{dx}y'\right) - x(9x^2+1)\,y' + (25x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(25x^2+1)y}{x^2(x^2+1)} + \frac{(9x^2+1)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{(9x^2+1)y'}{x(x^2+1)} + \frac{(25x^2+1)y}{x^2(x^2+1)} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{9x^2+1}{x(x^2+1)}, P_3(x) = \frac{25x^2+1}{x^2(x^2+1)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 1$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d}{dx}y'\right) - x(9x^2+1)\,y' + (25x^2+1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
- Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx} y'\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k- >k + 2 - m$

  $x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 (-1+r)^2 x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k (k+r-1)^2 + a_{k-2} (k-7+r)^2\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 1$
- Each term must be 0

  $a_1 r^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_k (k+r-1)^2 + a_{k-2} (k-7+r)^2 = 0$
- Shift index using $k- >k + 2$

  $a_{k+2} (k+1+r)^2 + a_k (k+r-5)^2 = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k (k+r-5)^2}{(k+1+r)^2}$

- Recursion relation for $r = 1$; series terminates at $k = 4$

  $a_{k+2} = -\frac{a_k (k-4)^2}{(k+2)^2}$
- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k (k-4)^2}{(k+2)^2}, a_1 = 0\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2y'' + 3x(-x^2+1)\,y' + (7x^2+1)\,y = 0$$

1.153.1 Solved as second order ode using Kovacic algorithm

Time used: 1.281 (sec)

Writing the ode as

$$9x^2y'' + (-3x^3+3x)\,y' + (7x^2+1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= -3x^3+3x \\ C &= 7x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 36x^2 - 9}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 36x^2 - 9 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 36x^2 - 9}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 290: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 4 \\
&= -2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{36} - 1 - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{6} - \frac{3}{x} - \frac{111}{4x^3} - \frac{999}{2x^5} - \frac{180819}{16x^7} - \frac{2292705}{8x^9} - \frac{249239511}{32x^{11}} - \frac{3548540907}{16x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{36}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 36x^2 - 9}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{x^2}{36} - 1\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{36} - 1 - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{6} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{6}} - 1\right) &&= -\frac{7}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{6}} - 1\right) &&= \frac{5}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 36x^2 - 9}{36x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{6}$	$-\frac{7}{2}$	$\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{5}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{5}{2} - \left(\frac{1}{2}\right) \\
&= 2
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + (-)\left(\frac{x}{6}\right) \\
&= \frac{1}{2x} - \frac{x}{6} \\
&= \frac{1}{2x} - \frac{x}{6}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{1}{2x} - \frac{x}{6}\right)(2x + a_1) + \left(\left(-\frac{1}{2x^2} - \frac{1}{6}\right) + \left(\frac{1}{2x} - \frac{x}{6}\right)^2 - \left(\frac{x^4 - 36x^2 - 9}{36x^2}\right)\right) = 0$$

$$\frac{x^2 a_1 + 2(6 + a_0)\, x + 3a_1}{3x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -6, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 6$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 - 6\right) \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{x}{6}\right) dx} \\
&= \left(x^2 - 6\right) \mathrm{e}^{-\frac{x^2}{12} + \frac{\ln(x)}{2}} \\
&= \left(x^2 - 6\right) \sqrt{x}\, \mathrm{e}^{-\frac{x^2}{12}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x^3+3x}{9x^2}\,dx} \\
&= z_1 e^{\frac{x^2}{12}-\frac{\ln(x)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x^2}{12}}}{x^{1/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{1/3}(x^2-6)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x^3+3x}{9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{x^2}{6}-\frac{\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{x^2}{6}-\frac{\ln(x)}{3}}}{x^{2/3}(x^2-6)^2}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{1/3}(x^2-6)\right) + c_2\left(x^{1/3}(x^2-6)\left(\int \frac{\mathrm{e}^{\frac{x^2}{6}-\frac{\ln(x)}{3}}}{x^{2/3}(x^2-6)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.153.2 Maple step by step solution

Let's solve

$9x^2\left(\frac{d}{dx}y'\right)+3x(-x^2+1)\,y'+(7x^2+1)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{(7x^2+1)y}{9x^2}+\frac{(x^2-1)y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'-\frac{(x^2-1)y'}{3x}+\frac{(7x^2+1)y}{9x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=-\frac{x^2-1}{3x}, P_3(x)=\frac{7x^2+1}{9x^2}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=\frac{1}{3}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=\frac{1}{9}$

- ◦ $x=0$is a regular singular point

Check to see if $x_0=0$ is a regular singular point

$x_0=0$

- Multiply by denominators

$9x^2\left(\frac{d}{dx}y'\right)-3x(x^2-1)\,y'+(7x^2+1)\,y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+3r)^2\, x^r + a_1(2+3r)^2\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-1)^2 - a_{k-2}(3k-13+3r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+3r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{3}$

- Each term must be 0

  $a_1(2+3r)^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(3k+3r-1)^2 + (-3k+13-3r)\, a_{k-2} = 0$

- Shift index using $k->k+2$

  $a_{k+2}(3k+5+3r)^2 + a_k(-3k-3r+7) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k(3k+3r-7)}{(3k+5+3r)^2}$

- Recursion relation for $r = \frac{1}{3}$; series terminates at $k = 2$

  $a_{k+2} = \frac{a_k(3k-6)}{(3k+6)^2}$

- Solution for $r = \frac{1}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = \frac{a_k(3k-6)}{(3k+6)^2}, a_1 = 0\right]$

Solve

$$x\left(x^{2}+1\right) y''+\left(-x^{2}+1\right) y'-8 x y=0$$

1.154.1 Solved as second order ode using Kovacic algorithm

Time used: 0.423 (sec)

Writing the ode as

$$\left(x^{3}+x\right) y''+\left(-x^{2}+1\right) y'-8 x y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{3}+x \\ B &= -x^{2}+1 \\ C &= -8 x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A} d x}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{35x^4 + 22x^2 - 1}{4\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 35x^4 + 22x^2 - 1$$
$$t = 4\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{35x^4 + 22x^2 - 1}{4\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 292: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} - \frac{15i}{4(x-i)} + \frac{15i}{4(x+i)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{35x^4 + 22x^2 - 1}{4\left(x^3 + x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{35}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{35x^4 + 22x^2 - 1}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+ + \alpha_{c_3}^+\right) \\ &= \frac{7}{2} - \left(\frac{7}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)} + (0) \\ &= \frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)} \\ &= \frac{1}{2x} + \frac{3x}{x^2+1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{3}{2(x-i)^2} - \frac{3}{2(x+i)^2}\right) + \left(\frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)}\right) dx} \\ &= \left(x^2+1\right)^{3/2}\sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+1}{x^3+x}\,dx} \\
&= z_1 e^{\frac{\ln\left(x^2+1\right)}{2}-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\sqrt{x^2+1}}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \left(x^2+1\right)^2
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+1}{x^3+x}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x^2+1)-\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\frac{1}{4\left(x^2+1\right)^2}+\frac{1}{2x^2+2}-\frac{\ln\left(x^2+1\right)}{2}+\ln\left(x\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(x^2+1\right)^2\right) + c_2\left(\left(x^2+1\right)^2\left(\frac{1}{4\left(x^2+1\right)^2}+\frac{1}{2x^2+2}-\frac{\ln\left(x^2+1\right)}{2}+\ln\left(x\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.154.2 Maple step by step solution

Let's solve

$x(x^2+1)\left(\frac{d}{dx}y'\right)+(-x^2+1)\,y'-8xy=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y'=\frac{8y}{x^2+1}+\frac{(x^2-1)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y'-\frac{(x^2-1)y'}{x(x^2+1)}-\frac{8y}{x^2+1}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{x^2-1}{x(x^2+1)}, P_3(x)=-\frac{8}{x^2+1}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\Big|_{x=0}=1$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=0$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x(x^2+1)\left(\frac{d}{dx}y'\right)+(-x^2+1)\,y'-8xy=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x\cdot y$ to series expansion

    $x\cdot y=\sum_{k=0}^{\infty}a_k x^{k+r+1}$

  - Shift index using $k->k-1$

    $x\cdot y=\sum_{k=1}^{\infty}a_{k-1}x^{k+r}$

  - Convert $x^m\cdot y'$ to series expansion for $m=0..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 1..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r^2 x^{-1+r} + a_1 (1+r)^2\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)^2 + a_{k-1}(k+r+1)\,(k-5+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 0$
- Each term must be 0

  $a_1 (1+r)^2 = 0$
- Each term in the series must be 0, giving the recursion relation

  $((a_{k-1} + a_{k+1})\, k - 5a_{k-1} + a_{k+1})\,(k+1) = 0$
- Shift index using $k->k+1$

  $((a_k + a_{k+2})\,(k+1) - 5a_k + a_{k+2})\,(k+2) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k (k-4)}{k+2}$
- Recursion relation for $r = 0$; series terminates at $k = 4$

  $a_{k+2} = -\frac{a_k (k-4)}{k+2}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k (k-4)}{k+2}, a_1 = 0\right]$

1.155 problem 157

Internal problem ID [8293]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 157
Date solved : `Monday, October 21, 2024 at 05:05:24 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + 2x(-x^2+4)\,y' + (7x^2+1)\,y = 0$$

1.155.1 Solved as second order ode using Kovacic algorithm

Time used: 0.770 (sec)

Writing the ode as

$$4x^2y'' + (-2x^3+8x)\,y' + (7x^2+1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -2x^3+8x \\ C &= 7x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 40x^2 - 4}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 40x^2 - 4 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 40x^2 - 4}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 294: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{16} - \frac{5}{2} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} - \frac{5}{x} - \frac{101}{2x^3} - \frac{1010}{x^5} - \frac{50601}{2x^7} - \frac{710030}{x^9} - \frac{21351501}{x^{11}} - \frac{672670100}{x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{4}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 40x^2 - 4}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{x^2}{16} - \frac{5}{2}\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{16} - \frac{5}{2} - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{4}\\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{4}} - 1\right) &&= -\frac{11}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{4}} - 1\right) &&= \frac{9}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 40x^2 - 4}{16x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{4}$	$-\frac{11}{2}$	$\frac{9}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{9}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right)\\
&= \frac{9}{2} - \left(\frac{1}{2}\right)\\
&= 4
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{1}{2x} + (-)\left(\frac{x}{4}\right) \\ &= \frac{1}{2x} - \frac{x}{4} \\ &= \frac{1}{2x} - \frac{x}{4}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(12x^2 + 6xa_3 + 2a_2) + 2\left(\frac{1}{2x} - \frac{x}{4}\right)(4x^3 + 3a_3x^2 + 2a_2x + a_1) + \left(\left(-\frac{1}{2x^2} - \frac{1}{4}\right) + \left(\frac{1}{2x} - \frac{x}{4}\right)^2 - \left(\frac{x^4 \cdots}{\cdots}\right.\right.$$

$$\frac{x^4 a_3 + 2(16 + a_2)x^3 + 3(a_1 + 6a_3)x^2 + 4(a_0 + 2a \cdots}{2x}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 32, a_1 = 0, a_2 = -16, a_3 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 16x^2 + 32$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x^4 - 16x^2 + 32\right) e^{\int \left(\frac{1}{2x} - \frac{x}{4}\right) dx} \\ &= \left(x^4 - 16x^2 + 32\right) e^{-\frac{x^2}{8} + \frac{\ln(x)}{2}} \\ &= \left(x^4 - 16x^2 + 32\right) \sqrt{x}\, e^{-\frac{x^2}{8}}\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x^3+8x}{4x^2}\,dx} \\
&= z_1 e^{\frac{x^2}{8}-\ln(x)} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x^2}{8}}}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^4 - 16x^2 + 32}{\sqrt{x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^3+8x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{x^2}{4}-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{x^2}{4}-2\ln(x)}x}{(x^4-16x^2+32)^2}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^4-16x^2+32}{\sqrt{x}}\right) + c_2\left(\frac{x^4-16x^2+32}{\sqrt{x}}\left(\int \frac{\mathrm{e}^{\frac{x^2}{4}-2\ln(x)}x}{(x^4-16x^2+32)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.155.2 Maple step by step solution

Let's solve

$4x^2 \left(\frac{d}{dx}y'\right) + 2x(-x^2+4)\, y' + (7x^2+1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(7x^2+1)y}{4x^2} + \frac{(x^2-4)y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' - \frac{(x^2-4)y'}{2x} + \frac{(7x^2+1)y}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = -\frac{x^2-4}{2x}, P_3(x) = \frac{7x^2+1}{4x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 2$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = \frac{1}{4}$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2 \left(\frac{d}{dx}y'\right) - 2(x^2-4)\, xy' + (7x^2+1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d}{dx}y'\right)$ to series expansion

$$x^2 \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 (1+2r)^2\, x^r + a_1 (3+2r)^2\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k (2k+2r+1)^2 - a_{k-2}(2k-11+2r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+2r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = -\frac{1}{2}$
- Each term must be 0
  $a_1 (3+2r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_k (2k+2r+1)^2 + (-2k+11-2r)\, a_{k-2} = 0$
- Shift index using $k- >k+2$
  $a_{k+2}(2k+5+2r)^2 + a_k(-2k-2r+7) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{a_k (2k+2r-7)}{(2k+5+2r)^2}$
- Recursion relation for $r = -\frac{1}{2}$; series terminates at $k = 4$
  $a_{k+2} = \frac{a_k (2k-8)}{(2k+4)^2}$
- Solution for $r = -\frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = \frac{a_k (2k-8)}{(2k+4)^2}, a_1 = 0\right]$$

1.156 problem 158

Internal problem ID [8294]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 158
Date solved : `Monday, October 21, 2024 at 05:05:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2(1+x)\,y''+8x^2y'+(1+x)\,y=0$$

1.156.1 Solved as second order ode using Kovacic algorithm

Time used: 0.191 (sec)

Writing the ode as

$$\left(4x^3+4x^2\right)y''+8x^2y'+(1+x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=4x^3+4x^2\\B&=8x^2\\C&=1+x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 296: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0\\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx}\\ &= e^{\int \frac{1}{2x} dx}\\ &= \sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{8x^2}{4x^3+4x^2}\, dx}\\ &= z_1 e^{-\ln(1+x)}\\ &= z_1\left(\frac{1}{1+x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{1+x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8x^2}{4x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x}}{1+x}\right) + c_2 \left(\frac{\sqrt{x}}{1+x}(\ln(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.157 problem 159

Internal problem ID [8295]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 159
Date solved : `Monday, October 21, 2024 at 05:05:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2(3+x)\,y''+3x(3+7x)\,y'+(3+4x)\,y=0$$

1.157.1 Solved as second order ode using Kovacic algorithm

Time used: 0.262 (sec)

Writing the ode as

$$\left(9x^3+27x^2\right)y''+\left(21x^2+9x\right)y'+(3+4x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^3+27x^2 \\ B &= 21x^2+9x \\ C &= 3+4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 298: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0 \\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{21x^2+9x}{9x^3+27x^2} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{6} - \ln(3+x)} \\ &= z_1 \left(\frac{1}{x^{1/6}\,(3+x)}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{3+x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{21x^2+9x}{9x^3+27x^2} dx}}{(y_1)^2} dx$$
$$= y_1 \int \frac{e^{-\frac{\ln(x)}{3} - 2\ln(3+x)}}{(y_1)^2} dx$$
$$= y_1 \left(\frac{x^2}{9+3x} + \frac{2x}{3+x} + \frac{3}{3+x} - \frac{2\ln(3+x)\,x}{3} - 2\ln(3+x) + \ln(x) + \frac{2\ln(3+x)\,(3+x)}{3} - \frac{x}{3} - 2 \right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x^{1/3}}{3+x} \right) + c_2 \left(\frac{x^{1/3}}{3+x} \left(\frac{x^2}{9+3x} + \frac{2x}{3+x} + \frac{3}{3+x} - \frac{2\ln(3+x)\,x}{3} - 2\ln(3+x) + \ln(x) + \frac{2\ln(3+x)\,(3+x)}{3} - \frac{x}{3} - 2 \right) \right)$$

Will add steps showing solving for IC soon.

1.157.2 Maple step by step solution

Let's solve
$9x^2(3+x)\left(\frac{d}{dx}y'\right) + 3x(3+7x)\,y' + (3+4x)\,y = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d}{dx}y'$

1.158 problem 160

Internal problem ID [8296]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 160
Date solved : `Monday, October 21, 2024 at 05:05:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(-x^2+2\right)y''-x\left(3x^2+2\right)y'+\left(-x^2+2\right)y=0$$

1.158.1 Solved as second order ode using Kovacic algorithm

Time used: 0.214 (sec)

Writing the ode as

$$\left(-x^4+2x^2\right)y''+\left(-3x^3-2x\right)y'+\left(-x^2+2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^4+2x^2\\B&=-3x^3-2x\\C&=-x^2+2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 300: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + (-)(0) \\
&= \frac{1}{2x} \\
&= \frac{1}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3x^3-2x}{-x^4+2x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{2} - \ln(x^2-2)} \\ &= z_1 \left(\frac{\sqrt{x}}{x^2-2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{x^2-2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x^3-2x}{-x^4+2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)-2\ln(x^2-2)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x}{x^2-2}\right) + c_2\left(\frac{x}{x^2-2}(\ln(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.158.2 Maple step by step solution

Let's solve

$x^2(-x^2+2)\left(\frac{d}{dx}y'\right) - x(3x^2+2)\,y' + (-x^2+2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{y}{x^2} - \frac{(3x^2+2)y'}{x(x^2-2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(3x^2+2)y'}{x(x^2-2)} + \frac{y}{x^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{3x^2+2}{x(x^2-2)}, P_3(x) = \frac{1}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 1$$

- ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(x^2-2)\left(\frac{d}{dx}y'\right) + x(3x^2+2)\,y' + (x^2-2)\,y = 0$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- □ Rewrite ODE with series expansions
  - ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

  - ◦ Shift index using $k->k-m$

    $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

  - ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

  - ◦ Shift index using $k->k+1-m$

    $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

    $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

  - ◦ Shift index using $k->k+2-m$

    $$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$-2a_0(-1+r)^2\,x^r - 2a_1r^2x^{1+r} + \left(\sum_{k=2}^{\infty}\left(-2a_k(k+r-1)^2 + a_{k-2}(k+r-1)^2\right)x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term must be 0
  $-2a_1r^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $-2\left(a_k - \frac{a_{k-2}}{2}\right)(k+r-1)^2 = 0$
- Shift index using $k- >k+2$
  $-2\left(a_{k+2} - \frac{a_k}{2}\right)(k+r+1)^2 = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{a_k}{2}$
- Recursion relation for $r = 1$
  $a_{k+2} = \frac{a_k}{2}$
- Solution for $r = 1$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = \frac{a_k}{2}, a_1 = 0\right]$

Solve

$$16x^2(x^2+1)\,y''+8x(9x^2+1)\,y'+(49x^2+1)\,y=0$$

1.159.1 Solved as second order ode using Kovacic algorithm

Time used: 0.266 (sec)

Writing the ode as

$$(16x^4+16x^2)\,y''+(72x^3+8x)\,y'+(49x^2+1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=16x^4+16x^2\\ B&=72x^3+8x\\ C&=49x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 302: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{72x^3+8x}{16x^4+16x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{4} - \ln(x^2+1)} \\ &= z_1 \left(\frac{1}{x^{1/4}(x^2+1)}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/4}}{x^2+1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{72x^3+8x}{16x^4+16x^2} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{2}-2\ln(x^2+1)}}{(y_1)^2} dx \\
&= y_1 \left(\ln(x) + \frac{x^4}{2x^2+2} + \frac{x^2}{x^2+1} + \frac{1}{2x^2+2} - \ln(x^2+1)\,x^2 - \ln(x^2+1) \right. \\
&\quad \left. + \ln(x^2+1)\,(x^2+1) - \frac{x^2}{2} - 1 \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/4}}{x^2+1} \right) \\
&\quad + c_2 \left(\frac{x^{1/4}}{x^2+1} \left(\ln(x) + \frac{x^4}{2x^2+2} + \frac{x^2}{x^2+1} + \frac{1}{2x^2+2} - \ln(x^2+1)\,x^2 - \ln(x^2+1) + \ln(x^2+1)\,(x^2+1) - \frac{x^2}{2} \right.\right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.159.2 Maple step by step solution

Let's solve

$16x^2(x^2+1)\left(\frac{d}{dx}y'\right) + 8x(9x^2+1)\,y' + (49x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(49x^2+1)y}{16x^2(x^2+1)} - \frac{(9x^2+1)y'}{2x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(9x^2+1)y'}{2x(x^2+1)} + \frac{(49x^2+1)y}{16x^2(x^2+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x)=\frac{9x^2+1}{2x(x^2+1)}, P_3(x)=\frac{49x^2+1}{16x^2(x^2+1)}\right]$

- $x \cdot P_2(x)$ is analytic at $x=0$

  $\left.(x \cdot P_2(x))\right|_{x=0}=\frac{1}{2}$
- $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0}=\frac{1}{16}$
- $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $16x^2(x^2+1)\left(\frac{d}{dx}y'\right)+8x(9x^2+1)y'+(49x^2+1)y=0$
- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m=0..2$

  $x^m \cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k->k-m$

  $x^m \cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot y'$ to series expansion for $m=1..3$

  $x^m \cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
- Shift index using $k->k+1-m$

  $x^m \cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m=2..4$

  $x^m \cdot \left(\frac{d}{dx}y'\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d}{dx}y'\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+4r)^2 x^r + a_1(3+4r)^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(4k+4r-1)^2 + a_{k-2}(4k+4r-1)^2\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+4r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = \frac{1}{4}$
- Each term must be 0

  $a_1(3+4r)^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $(4k+4r-1)^2 (a_k + a_{k-2}) = 0$
- Shift index using $k->k+2$

  $(4k+4r+7)^2 (a_{k+2} + a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -a_k$
- Recursion relation for $r = \frac{1}{4}$

  $a_{k+2} = -a_k$
- Solution for $r = \frac{1}{4}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+2} = -a_k, a_1 = 0\right]$

1.160 problem 162

Internal problem ID [8298]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 162
Date solved : `Monday, October 21, 2024 at 05:05:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(4+3x)\,y''-x(4-3x)\,y'+4y=0$$

1.160.1 Solved as second order ode using Kovacic algorithm

Time used: 0.218 (sec)

Writing the ode as

$$\left(3x^3+4x^2\right)y''+\left(3x^2-4x\right)y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^3+4x^2 \\ B &= 3x^2-4x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 304: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3x^2-4x}{3x^3+4x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{2} - \ln(4+3x)} \\ &= z_1 \left(\frac{\sqrt{x}}{4+3x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{4+3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^2-4x}{3x^3+4x^2}\,dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(x)-2\ln(4+3x)}}{(y_1)^2}\, dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x}{4+3x}\right) + c_2\left(\frac{x}{4+3x}(\ln(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.160.2 Maple step by step solution

1.161 problem 163

Internal problem ID [8299]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 163
Date solved : `Monday, October 21, 2024 at 05:05:31 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+3x+1\right)y''+8x^2(3+2x)\,y'+\left(9x^2+3x+1\right)y=0$$

1.161.1 Solved as second order ode using Kovacic algorithm

Time used: 0.195 (sec)

Writing the ode as

$$\left(4x^4+12x^3+4x^2\right)y''+\left(16x^3+24x^2\right)y'+\left(9x^2+3x+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+12x^3+4x^2 \\ B &= 16x^3+24x^2 \\ C &= 9x^2+3x+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 306: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{16x^3 + 24x^2}{4x^4 + 12x^3 + 4x^2} \, dx} \\ &= z_1 e^{-\ln(x^2 + 3x + 1)} \\ &= z_1 \left(\frac{1}{x^2 + 3x + 1}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{x^2 + 3x + 1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{16x^3+24x^2}{4x^4+12x^3+4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(x^2+3x+1)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\sqrt{x}}{x^2+3x+1}\right) + c_2\left(\frac{\sqrt{x}}{x^2+3x+1}(\ln(x))\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.161.2 Maple step by step solution

Let's solve

$4x^2(x^2+3x+1)\left(\frac{d}{dx}y'\right) + 8x^2(3+2x)\,y' + (9x^2+3x+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$
- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(9x^2+3x+1)y}{4x^2(x^2+3x+1)} - \frac{2(3+2x)y'}{x^2+3x+1}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{2(3+2x)y'}{x^2+3x+1} + \frac{(9x^2+3x+1)y}{4x^2(x^2+3x+1)} = 0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{2(3+2x)}{x^2+3x+1}, P_3(x) = \frac{9x^2+3x+1}{4x^2(x^2+3x+1)}\right]$
- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 0$
- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = \frac{1}{4}$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2(x^2+3x+1)\left(\frac{d}{dx}y'\right) + 8x^2(3+2x)\,y' + (9x^2+3x+1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 2..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- > k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- Shift index using $k- > k + 2 - m$

  $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)^2\,x^r + \left(a_1(1+2r)^2 + 3a_0(1+2r)^2\right)x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r-1)^2 + 3a_{k-1}(2k+2r\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{2}$

- Each term must be 0

  $a_1(1+2r)^2 + 3a_0(1+2r)^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = -3a_0$
- Each term in the series must be 0, giving the recursion relation

  $(2k+2r-1)^2 (a_k + 3a_{k-1} + a_{k-2}) = 0$
- Shift index using $k->k+2$

  $(2k+2r+3)^2 (a_{k+2} + 3a_{k+1} + a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -3a_{k+1} - a_k$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -3a_{k+1} - a_k$
- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -3a_{k+1} - a_k, a_1 = -3a_0\right]$

1.162 problem 164

Internal problem ID [8300]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 164
Date solved : `Monday, October 21, 2024 at 05:05:32 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-x)^2 y'' - x(-3x^2+2x+1)\, y' + (x^2+1)\, y = 0$$

1.162.1 Solved as second order ode using Kovacic algorithm

Time used: 0.207 (sec)

Writing the ode as

$$x^2(-1+x)^2 y'' + (3x^3-2x^2-x)\, y' + (x^2+1)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(-1+x)^2 \\ B &= 3x^3-2x^2-x \\ C &= x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 308: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{3x^3 - 2x^2 - x}{x^2(-1+x)^2} \, dx} \\ &= z_1 e^{\frac{\ln(x)}{2} - 2\ln(-1+x)} \\ &= z_1 \left(\frac{\sqrt{x}}{(-1+x)^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{(-1+x)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3-2x^2-x}{x^2(-1+x)^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)-4\ln(-1+x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x}{(-1+x)^2}\right) + c_2\left(\frac{x}{(-1+x)^2}(\ln(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.163 problem 165

Internal problem ID [8301]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 165
Date solved : `Monday, October 21, 2024 at 05:05:33 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2\left(x^2+x+1\right)y''+3x\left(13x^2+7x+1\right)y'+\left(25x^2+4x+1\right)y=0$$

1.163.1 Solved as second order ode using Kovacic algorithm

Time used: 0.320 (sec)

Writing the ode as

$$\left(9x^4+9x^3+9x^2\right)y''+\left(39x^3+21x^2+3x\right)y'+\left(25x^2+4x+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=9x^4+9x^3+9x^2\\B&=39x^3+21x^2+3x\\C&=25x^2+4x+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 310: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0 \\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{39x^3+21x^2+3x}{9x^4+9x^3+9x^2} \, dx} \\ &= z_1 e^{-\ln(x^2+x+1) - \frac{\ln(x)}{6}} \\ &= z_1 \left(\frac{1}{(x^2+x+1)\, x^{1/6}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{x^2 + x + 1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{39x^3+21x^2+3x}{9x^4+9x^3+9x^2}dx}}{(y_1)^2} dx$$
$$= y_1 \int \frac{e^{-2\ln(x^2+x+1)-\frac{\ln(x)}{3}}}{(y_1)^2} dx$$
$$= y_1 \left(2x - \frac{19}{24} + (x-1)^2 + \frac{x}{3x^2+3x+3} - \frac{x^5}{3(x^2+x+1)} - \frac{x^4}{3(x^2+x+1)} - \frac{x^3}{3(x^2+x+1)} + \frac{x^2}{3x^2+3x+3} + \frac{1}{3x^2+3x+3} + \frac{x^3}{3} - x^2 + \ln(x)\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1\left(\frac{x^{1/3}}{x^2+x+1}\right)$$
$$+ c_2\left(\frac{x^{1/3}}{x^2+x+1}\left(2x - \frac{19}{24} + (x-1)^2 + \frac{x}{3x^2+3x+3} - \frac{x^5}{3(x^2+x+1)} - \frac{x^4}{3(x^2+x+1)} - \frac{x^3}{3(x^2+x+1)} +\right.\right.$$

Will add steps showing solving for IC soon.

1.163.2 Maple step by step solution

Let's solve

$9x^2(x^2+x+1)\left(\frac{d}{dx}y'\right) + 3x(13x^2+7x+1)y' + (25x^2+4x+1)y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(25x^2+4x+1)y}{9x^2(x^2+x+1)} - \frac{(13x^2+7x+1)y'}{3x(x^2+x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(13x^2+7x+1)y'}{3x(x^2+x+1)} + \frac{(25x^2+4x+1)y}{9x^2(x^2+x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{13x^2+7x+1}{3x(x^2+x+1)}, P_3(x) = \frac{25x^2+4x+1}{9x^2(x^2+x+1)}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = \frac{1}{3}$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{1}{9}$

- ○ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- • Multiply by denominators

  $9x^2(x^2+x+1)\left(\frac{d}{dx}y'\right) + 3x(13x^2+7x+1)\,y' + (25x^2+4x+1)\,y = 0$

- • Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions

  - ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ○ Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - ○ Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - ○ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..4$

    $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  - ○ Shift index using $k- >k+2-m$

    $x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+3r)^2 x^r + \left(a_1(2+3r)^2 + a_0(2+3r)^2\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-1)^2 + a_{k-1}(3k+3r-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+3r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = \frac{1}{3}$
- Each term must be 0
  $a_1(2+3r)^2 + a_0(2+3r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = -a_0$
- Each term in the series must be 0, giving the recursion relation
  $(3k+3r-1)^2 (a_k + a_{k-1} + a_{k-2}) = 0$
- Shift index using $k- >k+2$
  $(3k+3r+5)^2 (a_{k+2} + a_{k+1} + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -a_{k+1} - a_k$
- Recursion relation for $r = \frac{1}{3}$
  $a_{k+2} = -a_{k+1} - a_k$
- Solution for $r = \frac{1}{3}$
  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -a_{k+1} - a_k, a_1 = -a_0\right]$

1.164 problem 166

Internal problem ID [8302]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 166
Date solved : `Monday, October 21, 2024 at 05:05:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(2+x)\,y''-x(4-7x)\,y'-(5-3x)\,y=0$$

1.164.1 Solved as second order ode using Kovacic algorithm

Time used: 0.296 (sec)

Writing the ode as

$$\left(2x^3+4x^2\right)y''+\left(7x^2-4x\right)y'+(3x-5)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x^3+4x^2\\B&=7x^2-4x\\C&=3x-5\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3x^2 - 32x + 128}{16\left(x^2 + 2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -3x^2 - 32x + 128$$
$$t = 16\left(x^2 + 2x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3x^2 - 32x + 128}{16\left(x^2 + 2x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 312: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{2x} + \frac{5}{2(2+x)} + \frac{45}{16(2+x)^2} + \frac{2}{x^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{45}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 - 32x + 128}{16(x^2 + 2x)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^2-32x+128}{16\left(x^2+2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-2	2	0	$\frac{9}{4}$	$-\frac{5}{4}$
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=\frac{3}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right) \\
&= \frac{3}{4} - \left(\frac{3}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= -\frac{5}{4\left(2+x\right)} + \frac{2}{x} + (0) \\
&= -\frac{5}{4\left(2+x\right)} + \frac{2}{x} \\
&= \frac{3x+16}{4x\left(2+x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{5}{4\left(2+x\right)} + \frac{2}{x}\right)(0) + \left(\left(\frac{5}{4\left(2+x\right)^2} - \frac{2}{x^2}\right) + \left(-\frac{5}{4\left(2+x\right)} + \frac{2}{x}\right)^2 - \left(\frac{-3x^2-32x+128}{16\left(x^2+2x\right)^2}\right)\right) = 0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{5}{4(2+x)} + \frac{2}{x}\right) dx} \\
&= \frac{x^2}{\left(2+x\right)^{5/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^2-4x}{2x^3+4x^2}\, dx} \\
&= z_1 e^{\frac{\ln(x)}{2} - \frac{9\ln(2+x)}{4}} \\
&= z_1 \left(\frac{\sqrt{x}}{\left(2+x\right)^{9/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{x^{5/2}}{(2+x)^{7/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^2-4x}{2x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(x)-\frac{9\ln(2+x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{-\frac{11(2+x)^{5/2}}{8}+\frac{10(2+x)^{3/2}}{3}-\frac{5\sqrt{2+x}}{2}}{x^3} - \frac{5\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{16}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{5/2}}{(2+x)^{7/2}}\right) \\
&\quad + c_2\left(\frac{x^{5/2}}{(2+x)^{7/2}}\left(\frac{-\frac{11(2+x)^{5/2}}{8}+\frac{10(2+x)^{3/2}}{3}-\frac{5\sqrt{2+x}}{2}}{x^3} - \frac{5\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{16}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.164.2 Maple step by step solution

Let's solve

$2x^2(2+x)\left(\frac{d}{dx}y'\right)-x(4-7x)\,y'-(5-3x)\,y=0$

- Highest derivative means the order of the ODE is 2

$\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y'=-\frac{(3x-5)y}{2x^2(2+x)}-\frac{(7x-4)y'}{2x(2+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d}{dx}y'+\frac{(7x-4)y'}{2x(2+x)}+\frac{(3x-5)y}{2x^2(2+x)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{7x-4}{2x(2+x)},P_3(x)=\frac{3x-5}{2x^2(2+x)}\right]$

- ◦ $(2+x)\cdot P_2(x)$ is analytic at $x=-2$

$\left((2+x)\cdot P_2(x)\right)\bigg|_{x=-2}=\frac{9}{2}$

- ◦ $(2+x)^2\cdot P_3(x)$ is analytic at $x=-2$

$\left((2+x)^2\cdot P_3(x)\right)\bigg|_{x=-2}=0$

- ◦ $x=-2$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-2$

- Multiply by denominators

$2x^2(2+x)\left(\frac{d}{dx}y'\right)+x(7x-4)\,y'+(3x-5)\,y=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

$(2u^3-8u^2+8u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(7u^2-32u+36)\left(\frac{d}{du}y(u)\right)+(3u-11)\,y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

$u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ◦ Shift index using $k->k-m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$4a_0r(7+2r)\, u^{-1+r} + \left(4a_1(1+r)\,(9+2r) - a_0(8r^2+24r+11)\right) u^r + \left(\sum_{k=1}^{\infty} (4a_{k+1}(k+r+1)\,(2k$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$4r(7+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{7}{2}\right\}$$

- Each term must be 0

$$4a_1(1+r)\,(9+2r) - a_0(8r^2+24r+11) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$2(-4a_k + a_{k-1} + 4a_{k+1})\, k^2 + \left(4(-4a_k + a_{k-1} + 4a_{k+1})\, r - 24a_k + a_{k-1} + 44a_{k+1}\right) k + 2(-4a_k +$$

- Shift index using $k- >k+1$

$$2(-4a_{k+1} + a_k + 4a_{k+2})\,(k+1)^2 + \left(4(-4a_{k+1} + a_k + 4a_{k+2})\, r - 24a_{k+1} + a_k + 44a_{k+2}\right)(k+1)$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 4kra_k - 16kra_{k+1} + 2r^2a_k - 8r^2a_{k+1} + 5ka_k - 40ka_{k+1} + 5ra_k - 40ra_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+4kr+2r^2+15k+15r+22)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 5ka_k - 40ka_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+15k+22)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 5ka_k - 40ka_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+15k+22)}, 36a_1 - 11a_0 = 0\right]$$

- Revert the change of variables $u = 2+x$

$$\left[y = \sum_{k=0}^{\infty} a_k (2+x)^k, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + 5k a_k - 40k a_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+15k+22)}, 36a_1 - 11a_0 = 0\right]$$

- Recursion relation for $r = -\frac{7}{2}$

$$a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} - 9k a_k + 16k a_{k+1} + 10a_k - a_{k+1}}{4(2k^2+k-6)}$$

- Solution for $r = -\frac{7}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{7}{2}}, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} - 9k a_k + 16k a_{k+1} + 10a_k - a_{k+1}}{4(2k^2+k-6)}, -20a_1 - 25a_0 = 0\right]$$

- Revert the change of variables $u = 2 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (2+x)^{k-\frac{7}{2}}, a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} - 9k a_k + 16k a_{k+1} + 10a_k - a_{k+1}}{4(2k^2+k-6)}, -20a_1 - 25a_0 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (2+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (2+x)^{k-\frac{7}{2}}\right), a_{k+2} = -\frac{2k^2 a_k - 8k^2 a_{k+1} + 5k a_k - 40k a_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+15k+22)}, 36a\right.$$

1.165 problem 167

Internal problem ID [8303]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 167
Date solved : `Monday, October 21, 2024 at 05:05:35 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''+x(8-9x)\,y'+(6-3x)\,y=0$$

1.165.1 Solved as second order ode using Kovacic algorithm

Time used: 0.263 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+\left(-9x^2+8x\right)y'+(6-3x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -2x^3+x^2 \\ B &= -9x^2+8x \\ C &= 6-3x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{21x^2 - 20x + 24}{4\left(2x^2 - x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 21x^2 - 20x + 24 \\
t &= 4\left(2x^2 - x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{21x^2 - 20x + 24}{4\left(2x^2 - x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 314: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{77}{16\left(x - \frac{1}{2}\right)^2} - \frac{19}{x - \frac{1}{2}} + \frac{6}{x^2} + \frac{19}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{77}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{11}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{7}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading

coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{21x^2 - 20x + 24}{4(2x^2 - x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{21}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{21x^2 - 20x + 24}{4(2x^2 - x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2
$\frac{1}{2}$	2	0	$\frac{11}{4}$	$-\frac{7}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^+ - (\alpha_{c_1}^- + \alpha_{c_2}^+)\\ &= \frac{7}{4} - \left(\frac{3}{4}\right)\\ &= 1\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{2}{x} + \frac{11}{4\left(x-\frac{1}{2}\right)} + (0) \\
&= -\frac{2}{x} + \frac{11}{4\left(x-\frac{1}{2}\right)} \\
&= \frac{4+3x}{4x^2-2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{2}{x} + \frac{11}{4\left(x-\frac{1}{2}\right)}\right)(1) + \left(\left(\frac{2}{x^2} - \frac{11}{4\left(x-\frac{1}{2}\right)^2}\right) + \left(-\frac{2}{x} + \frac{11}{4\left(x-\frac{1}{2}\right)}\right)^2 - \left(\frac{21x^2-20x+24}{4\left(2x^2-x\right)^2}\right)\right)
$$

$$
\frac{4-3a_0}{x\left(-1+2x\right)} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{a_0 = \frac{4}{3}\right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + \frac{4}{3}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{4}{3}\right) e^{\int \left(-\frac{2}{x} + \frac{11}{4\left(x-\frac{1}{2}\right)}\right) dx} \\
&= \left(x + \frac{4}{3}\right) e^{-2\ln(x) + \frac{11\ln(-1+2x)}{4}} \\
&= \frac{\left(x+\frac{4}{3}\right)\left(-1+2x\right)^{11/4}}{x^2}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-9x^2+8x}{-2x^3+x^2}\,dx} \\
&= z_1 e^{-4\ln(x)+\frac{7\ln(-1+2x)}{4}} \\
&= z_1\left(\frac{(-1+2x)^{7/4}}{x^4}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(-1+2x)^{9/2}\,(4+3x)}{3x^6}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-9x^2+8x}{-2x^3+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-8\ln(x)+\frac{7\ln(-1+2x)}{2}}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{(231x^3-198x^2+66x-8)\,x^8 \mathrm{e}^{-8\ln(x)+\frac{7\ln(-1+2x)}{2}}}{385\,(4+3x)\,(-1+2x)^8}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{(-1+2x)^{9/2}\,(4+3x)}{3x^6}\right) \\
&\quad + c_2\left(\frac{(-1+2x)^{9/2}\,(4+3x)}{3x^6}\left(-\frac{(231x^3-198x^2+66x-8)\,x^8 \mathrm{e}^{-8\ln(x)+\frac{7\ln(-1+2x)}{2}}}{385\,(4+3x)\,(-1+2x)^8}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.165.2 Maple step by step solution

Let's solve

$x^2(1-2x)\left(\frac{d}{dx}y'\right)+x(8-9x)\,y'+(6-3x)\,y=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

  $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(6+r)\,(1+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r+6)\,(k+r+1) + a_{k-1}(k+2+r)\,(2k-1+2r)\right) x^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-(6+r)\,(1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-6, -1\}$$

- Each term in the series must be 0, giving the recursion relation

$$2(k+2+r)\left(k-\frac{1}{2}+r\right)a_{k-1} - a_k(k+r+6)\,(k+r+1) = 0$$

- Shift index using $k->k+1$

$$2(k+r+3)\left(k+\frac{1}{2}+r\right)a_k - a_{k+1}(k+7+r)\,(k+2+r) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{(k+r+3)(2k+2r+1)a_k}{(k+7+r)(k+2+r)}$$

- Recursion relation for $r = -6$; series terminates at $k = 3$

$$a_{k+1} = \frac{(k-3)(2k-11)a_k}{(k+1)(k-4)}$$

- Apply recursion relation for $k = 0$

$$a_1 = -\frac{33a_0}{4}$$

- Apply recursion relation for $k = 1$

$$a_2 = -3a_1$$

- Express in terms of a_0

$$a_2 = \frac{99a_0}{4}$$

- Apply recursion relation for $k = 2$

$$a_3 = -\frac{7a_2}{6}$$

- Express in terms of a_0

$a_3 = -\frac{231 a_0}{8}$

- Terminating series solution of the ODE for $r = -6$. Use reduction of order to find the second

  $y = a_0 \cdot \left(-\frac{231}{8}x^3 + \frac{99}{4}x^2 - \frac{33}{4}x + 1\right)$

- Recursion relation for $r = -1$

  $a_{k+1} = \frac{(k+2)(2k-1)a_k}{(k+6)(k+1)}$

- Solution for $r = -1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = \frac{(k+2)(2k-1)a_k}{(k+6)(k+1)}\right]$

- Combine solutions and rename parameters

  $\left[y = a_0 \cdot \left(-\frac{231}{8}x^3 + \frac{99}{4}x^2 - \frac{33}{4}x + 1\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), b_{k+1} = \frac{(k+2)(2k-1)b_k}{(k+6)(k+1)}\right]$

1.166 problem 168

Internal problem ID [8304]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 168
Date solved : `Monday, October 21, 2024 at 05:05:36 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+1\right)y''+x\left(10x^2+3\right)y'-\left(-14x^2+15\right)y=0$$

1.166.1 Solved as second order ode using Kovacic algorithm

Time used: 0.392 (sec)

Writing the ode as

$$\left(x^4+x^2\right)y''+\left(10x^3+3x\right)y'+\left(14x^2-15\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= 10x^3+3x \\ C &= 14x^2-15 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \\ = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{24x^4 + 66x^2 + 63}{4\left(x^3 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 24x^4 + 66x^2 + 63$$
$$t = 4\left(x^3 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{24x^4 + 66x^2 + 63}{4\left(x^3 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 316: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{21}{16(x-i)^2} + \frac{21}{16(x+i)^2} + \frac{99i}{16(x-i)} - \frac{99i}{16(x+i)} + \frac{63}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{63}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{24x^4 + 66x^2 + 63}{4\left(x^3 + x\right)^2}
$$

Since the $\gcd(s, t) = 1$. This gives $b = 6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{24x^4 + 66x^2 + 63}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{9}{2}$	$-\frac{7}{2}$
i	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$-i$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 3$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 3 - (3) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{9}{2x} - \frac{3}{4\,(x-i)} - \frac{3}{4\,(x+i)} + (0) \\
&= \frac{9}{2x} - \frac{3}{4\,(x-i)} - \frac{3}{4\,(x+i)} \\
&= \frac{9}{2x} - \frac{3x}{2x^2+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{9}{2x} - \frac{3}{4\,(x-i)} - \frac{3}{4\,(x+i)}\right)(0) + \left(\left(-\frac{9}{2x^2} + \frac{3}{4\,(x-i)^2} + \frac{3}{4\,(x+i)^2}\right) + \left(\frac{9}{2x} - \frac{3}{4\,(x-i)} - \frac{}{4(}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{9}{2x} - \frac{3}{4(x-i)} - \frac{3}{4(x+i)}\right) dx} \\
&= \frac{x^{9/2}}{\left(x^2+1\right)^{3/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{10x^3+3x}{x^4+x^2}\,dx} \\
&= z_1 e^{-\frac{7\ln\left(x^2+1\right)}{4}-\frac{3\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{\left(x^2+1\right)^{7/4} x^{3/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^3}{\left(x^2+1\right)^{5/2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{10x^3+3x}{x^4+x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{7\ln\left(x^2+1\right)}{2}-3\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(-\frac{\left(x^2+1\right)^{5/2}}{8x^8}+\frac{\left(x^2+1\right)^{5/2}}{16x^6}-\frac{\left(x^2+1\right)^{5/2}}{64x^4}-\frac{\left(x^2+1\right)^{5/2}}{128x^2}+\frac{\left(x^2+1\right)^{3/2}}{128}\right. \\
&\qquad \left.+\frac{3\sqrt{x^2+1}}{128}-\frac{3\,\mathrm{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)}{128}\right)
\end{aligned}
$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x^3}{(x^2+1)^{5/2}}\right)$$
$$+ c_2 \left(\frac{x^3}{(x^2+1)^{5/2}} \left(-\frac{(x^2+1)^{5/2}}{8x^8} + \frac{(x^2+1)^{5/2}}{16x^6} - \frac{(x^2+1)^{5/2}}{64x^4} - \frac{(x^2+1)^{5/2}}{128x^2} + \frac{(x^2+1)^{3/2}}{128} + \frac{3\sqrt{x^2+1}}{128} - \frac{3}{}\right.\right.$$

Will add steps showing solving for IC soon.

1.166.2 Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d}{dx}y'\right) + x(10x^2+3)\,y' - (-14x^2+15)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(14x^2-15)y}{x^2(x^2+1)} - \frac{(10x^2+3)y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(10x^2+3)y'}{x(x^2+1)} + \frac{(14x^2-15)y}{x^2(x^2+1)} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = \frac{10x^2+3}{x(x^2+1)}, P_3(x) = \frac{14x^2-15}{x^2(x^2+1)}\right]$

  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 3$

  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -15$

  - ◦ $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d}{dx}y'\right) + x(10x^2+3)\,y' + (14x^2-15)\,y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

  - Shift index using $k- > k - m$

    $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

  - Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

  - Shift index using $k- > k + 1 - m$

    $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

  - Convert $x^m \cdot \left(\frac{d}{dx} y'\right)$ to series expansion for $m = 2..4$

    $$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

  - Shift index using $k- > k + 2 - m$

    $$x^m \cdot \left(\frac{d}{dx} y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(5+r)\,(-3+r)\, x^r + a_1(6+r)\,(-2+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r+5)\,(k+r-3) + a_{k-2}(k+r-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(5+r)\,(-3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-5, 3\}$
- Each term must be 0

  $a_1(6+r)\,(-2+r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k+r+5)\,(a_k(k+r-3) + a_{k-2}(k+r)) = 0$
- Shift index using $k- > k + 2$

  $(k+r+7)\,(a_{k+2}(k+r-1) + a_k(k+r+2)) = 0$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k(k+r+2)}{k+r-1}$$

- Recursion relation for $r = -5$

$$a_{k+2} = -\frac{a_k(k-3)}{k-6}$$

- Series not valid for $r = -5$, division by 0 in the recursion relation at $k = 6$

$$a_{k+2} = -\frac{a_k(k-3)}{k-6}$$

- Recursion relation for $r = 3$

$$a_{k+2} = -\frac{a_k(k+5)}{k+2}$$

- Solution for $r = 3$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = -\frac{a_k(k+5)}{k+2}, a_1 = 0\right]$$

1.167 problem 169

Internal problem ID [8305]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 169
Date solved : `Monday, October 21, 2024 at 05:05:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(-2x^2+1)\,y''+x(-13x^2+7)\,y'-14x^2y=0$$

1.167.1 Solved as second order ode using Kovacic algorithm

Time used: 0.360 (sec)

Writing the ode as

$$(-2x^4+x^2)\,y''+(-13x^3+7x)\,y'-14x^2y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-2x^4+x^2\\B&=-13x^3+7x\\C&=-14x^2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5x^4 - 68x^2 + 35}{4(2x^3 - x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 5x^4 - 68x^2 + 35$$
$$t = 4(2x^3 - x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5x^4 - 68x^2 + 35}{4(2x^3 - x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 318: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^3 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4x^2} + \frac{9}{64\left(x - \frac{\sqrt{2}}{2}\right)^2} + \frac{9}{64\left(x + \frac{\sqrt{2}}{2}\right)^2} - \frac{279\sqrt{2}}{64\left(x - \frac{\sqrt{2}}{2}\right)} + \frac{279\sqrt{2}}{64\left(x + \frac{\sqrt{2}}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = \frac{\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{9}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{8} \end{aligned}$$

For the pole at $x = -\frac{\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{9}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{5x^4 - 68x^2 + 35}{4\left(2x^3 - x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{5x^4 - 68x^2 + 35}{4\left(2x^3 - x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
$\frac{\sqrt{2}}{2}$	2	0	$\frac{9}{8}$	$-\frac{1}{8}$
$-\frac{\sqrt{2}}{2}$	2	0	$\frac{9}{8}$	$-\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+ + \alpha_{c_3}^+\right) \\ &= -\frac{1}{4} - \left(-\frac{1}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x-c_3} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{5}{2x} + \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)} + \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)} + (-)\,(0) \\ &= -\frac{5}{2x} + \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)} + \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)} \\ &= \frac{-x^2+5}{4x^3-2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{2x} + \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)} + \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)} \right)(0) + \left(\left(\frac{5}{2x^2} - \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)^2} - \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)^2} \right) + \left(-\frac{5}{2x} + \right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{5}{2x}+\frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)}+\frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)}\right)dx} \\
&= \frac{\left(2x-\sqrt{2}\right)^{9/8}\left(2x+\sqrt{2}\right)^{9/8}}{x^{5/2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-13x^3+7x}{-2x^4+x^2}\, dx} \\
&= z_1 e^{-\frac{7\ln(x)}{2}+\frac{\ln\left(2x^2-1\right)}{8}} \\
&= z_1 \left(\frac{\left(2x^2-1\right)^{1/8}}{x^{7/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{2\left(2x^2-1\right)^{5/4} 2^{1/8}}{x^6}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-13x^3+7x}{-2x^4+x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-7\ln(x)+\frac{\ln\left(2x^2-1\right)}{4}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{\left(5x^4-20x^2+8\right) x^7 \mathrm{e}^{-7\ln(x)+\frac{\ln\left(2x^2-1\right)}{4}} 2^{3/4}}{120\left(2x^2-1\right)^{3/2}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{2(2x^2-1)^{5/4} 2^{1/8}}{x^6}\right) \\
&\quad + c_2 \left(\frac{2(2x^2-1)^{5/4} 2^{1/8}}{x^6} \left(\frac{(5x^4-20x^2+8)\, x^7 \mathrm{e}^{-7\ln(x)+\frac{\ln(2x^2-1)}{4}} 2^{3/4}}{120\,(2x^2-1)^{3/2}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

1.167.2 Maple step by step solution

Let's solve

$x^2(-2x^2+1)\left(\frac{d}{dx}y'\right) + x(-13x^2+7)\,y' - 14x^2y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{14y}{2x^2-1} - \frac{(13x^2-7)y'}{x(2x^2-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(13x^2-7)y'}{x(2x^2-1)} + \frac{14y}{2x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{13x^2-7}{x(2x^2-1)}, P_3(x) = \frac{14}{2x^2-1}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x=0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = 7$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

$$x(2x^2-1)\left(\frac{d}{dx}y'\right)+(13x^2-7)\,y'+14yx=0$$

- Assume series solution for y

$$y=\sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

  ◦ Convert $x\cdot y$ to series expansion

$$x\cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+1}$$

  ◦ Shift index using $k->k-1$

$$x\cdot y=\sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=0..2$

$$x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

  ◦ Shift index using $k->k+1-m$

$$x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y'\right)$ to series expansion for $m=1..3$

$$x^m\cdot\left(\frac{d}{dx}y'\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

  ◦ Shift index using $k->k+2-m$

$$x^m\cdot\left(\frac{d}{dx}y'\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0r(6+r)\,x^{-1+r}-a_1(1+r)\,(7+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(-a_{k+1}(k+r+1)\,(k+7+r)+a_{k-1}(2k+5+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(6+r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\{-6,0\}$$

- Each term must be 0

$$-a_1(1+r)\,(7+r)=0$$

- Each term in the series must be 0, giving the recursion relation

$$2\left(\left(k+r+\frac{5}{2}\right)a_{k-1}-\frac{a_{k+1}(k+7+r)}{2}\right)(k+r+1)=0$$

- Shift index using $k->k+1$

$$2\left(\left(k+\frac{7}{2}+r\right)a_k-\frac{a_{k+2}(k+8+r)}{2}\right)(k+r+2)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=\frac{(2k+2r+7)a_k}{k+8+r}$$

- Recursion relation for $r=-6$

$$a_{k+2}=\frac{(2k-5)a_k}{k+2}$$

- Solution for $r=-6$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k-6}, a_{k+2}=\frac{(2k-5)a_k}{k+2}, 5a_1=0\right]$$

- Recursion relation for $r=0$

$$a_{k+2}=\frac{(2k+7)a_k}{k+8}$$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k}, a_{k+2}=\frac{(2k+7)a_k}{k+8}, -7a_1=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k x^{k-6}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k}\right), a_{k+2}=\frac{(2k-5)a_k}{k+2}, 5a_1=0, b_{k+2}=\frac{(2k+7)b_k}{k+8}, -7b_1=0\right]$$

1.168 problem 170

Internal problem ID [8306]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 170
Date solved : `Monday, October 21, 2024 at 05:05:38 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2(1+x)\,y''+4x(1+2x)\,y'-(1+3x)\,y=0$$

1.168.1 Solved as second order ode using Kovacic algorithm

Time used: 0.263 (sec)

Writing the ode as

$$\left(4x^3+4x^2\right)y''+\left(8x^2+4x\right)y'+(-3x-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^3+4x^2 \\ B &= 8x^2+4x \\ C &= -3x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x + 4}{4x(1 + x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3x + 4$$
$$t = 4x(1 + x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x + 4}{4x(1 + x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 320: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 3 - 1 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x(1+x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= 1 \\
\alpha_c^- &= 1
\end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{x} - \frac{1}{4(1+x)^2} - \frac{1}{1+x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x+4}{4x(1+x)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2}\\ \alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{3x+4}{4x\,(1+x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	1	0	0	1
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=\frac{3}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^{+}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right)\\ &= \frac{3}{2}-\left(\frac{3}{2}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2} \right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{x} + \frac{1}{2 + 2x} + (0) \\
&= \frac{1}{x} + \frac{1}{2 + 2x} \\
&= \frac{1}{x} + \frac{1}{2 + 2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{1}{x} + \frac{1}{2 + 2x}\right)(0) + \left(\left(-\frac{1}{x^2} - \frac{1}{2(1 + x)^2}\right) + \left(\frac{1}{x} + \frac{1}{2 + 2x}\right)^2 - \left(\frac{3x + 4}{4x(1 + x)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{x} + \frac{1}{2 + 2x}\right) dx} \\
&= \sqrt{1 + x}\, x
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{8x^2 + 4x}{4x^3 + 4x^2} \, dx} \\
&= z_1 e^{-\frac{\ln(x(1 + x))}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x(1 + x)}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{\sqrt{1+x}\, x}{\sqrt{x\,(1+x)}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{8x^2+4x}{4x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x(1+x))}}{(y_1)^2}\, dx \\ &= y_1 \left(\ln(1+x) - \frac{1}{x} - \ln(x) \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\sqrt{1+x}\, x}{\sqrt{x\,(1+x)}} \right) + c_2 \left(\frac{\sqrt{1+x}\, x}{\sqrt{x\,(1+x)}} \left(\ln(1+x) - \frac{1}{x} - \ln(x) \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.168.2 Maple step by step solution

Let's solve

$4x^2(1+x)\left(\frac{d}{dx}y'\right) + 4x(1+2x)\, y' - (1+3x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = \frac{(1+3x)y}{4x^2(1+x)} - \frac{(1+2x)y'}{x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(1+2x)y'}{x(1+x)} - \frac{(1+3x)y}{4x^2(1+x)} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{1+2x}{x(1+x)}, P_3(x)=-\frac{1+3x}{4x^2(1+x)}\right]$
  - $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((1+x)\cdot P_2(x)\right)\bigg|_{x=-1}=1$
  - $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((1+x)^2\cdot P_3(x)\right)\bigg|_{x=-1}=0$
  - $x=-1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0=-1$
- Multiply by denominators

  $4x^2(1+x)\left(\frac{d}{dx}y'\right)+4x(1+2x)\,y'+(-3x-1)\,y=0$
- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(4u^3-8u^2+4u)\left(\frac{d}{du}\frac{d}{du}y(u)\right)+(8u^2-12u+4)\left(\frac{d}{du}y(u)\right)+(-3u+2)\,y(u)=0$
- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

    $u^m\cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$
  - Shift index using $k->k-m$

    $u^m\cdot y(u)=\sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m=1..3$

    $u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $$u^m\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

  Rewrite ODE with series expansions

  $$4a_0r^2u^{-1+r}+\left(4a_1(1+r)^2-2a_0(4r^2+2r-1)\right)u^r+\left(\sum_{k=1}^{\infty}\left(4a_{k+1}(k+1+r)^2-2a_k(4k^2+8kr\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$4r^2=0$$

- Values of r that satisfy the indicial equation

  $$r=0$$

- Each term must be 0

  $$4a_1(1+r)^2-2a_0(4r^2+2r-1)=0$$

- Each term in the series must be 0, giving the recursion relation

  $$(4k^2-4k-3)\,a_{k-1}+(-8k^2-4k+2)\,a_k+4a_{k+1}(k+1)^2=0$$

- Shift index using $k- >k+1$

  $$\left(4(k+1)^2-4k-7\right)a_k+\left(-8(k+1)^2-4k-2\right)a_{k+1}+4a_{k+2}(k+2)^2=0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2}$$

- Recursion relation for $r=0$

  $$a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2}$$

- Solution for $r=0$

  $$\left[y(u)=\sum_{k=0}^{\infty}a_ku^k,a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2},4a_1+2a_0=0\right]$$

- Revert the change of variables $u=1+x$

  $$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^k,a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2},4a_1+2a_0=0\right]$$

1.169 problem 171

Internal problem ID [8307]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 171
Date solved : `Monday, October 21, 2024 at 05:05:39 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(2+3x)\,y''+x(4+21x)\,y'-(1-9x)\,y=0$$

1.169.1 Solved as second order ode using Kovacic algorithm

Time used: 0.269 (sec)

Writing the ode as

$$\left(6x^3+4x^2\right)y''+\left(21x^2+4x\right)y'+(9x-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=6x^3+4x^2\\B&=21x^2+4x\\C&=9x-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-27x - 48}{16x\left(2 + 3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -27x - 48$$
$$t = 16x(2 + 3x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-27x - 48}{16x\left(2 + 3x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 322: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 3 - 1 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x(2+3x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = -\frac{2}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16\left(x+\frac{2}{3}\right)^2} + \frac{3}{4\left(x+\frac{2}{3}\right)} - \frac{3}{4x}$$

For the pole at $x = -\frac{2}{3}$ let b be the coefficient of $\frac{1}{\left(x+\frac{2}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-27x - 48}{16x\left(2+3x\right)^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{4} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{-27x-48}{16x\left(2+3x\right)^{2}}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	1	0	0	1
$-\frac{2}{3}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=\frac{3}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right) \\
&= \frac{3}{4}-\left(\frac{3}{4}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)} + (0) \\
&= \frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)} \\
&= \frac{8+9x}{12x^2+8x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)}\right)(0) + \left(\left(-\frac{1}{x^2} + \frac{1}{4\left(x+\frac{2}{3}\right)^2}\right) + \left(\frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)}\right)^2 - \left(\frac{-27x-48}{16x\left(2+3x\right)^2}\right)\right) = 0
$$

$$
0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)}\right) dx} \\
&= \frac{x}{\left(2+3x\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{21x^2+4x}{6x^3+4x^2} \, dx} \\
&= z_1 e^{-\frac{\ln(x)}{2} - \frac{5\ln(2+3x)}{4}} \\
&= z_1 \left(\frac{1}{\sqrt{x}\,\left(2+3x\right)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{(2+3x)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{21x^2+4x}{6x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)-\frac{5\ln(2+3x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{\sqrt{2+3x}}{x} - \frac{3\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{2+3x}\,\sqrt{2}}{2}\right)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x}}{(2+3x)^{3/2}}\right) + c_2 \left(\frac{\sqrt{x}}{(2+3x)^{3/2}} \left(-\frac{\sqrt{2+3x}}{x} - \frac{3\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{2+3x}\,\sqrt{2}}{2}\right)}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.169.2 Maple step by step solution

Let's solve

$2x^2(2+3x)\left(\frac{d}{dx}y'\right) + x(4+21x)\, y' - (1-9x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

$\frac{d}{dx}y' = -\frac{(9x-1)y}{2x^2(2+3x)} - \frac{(4+21x)y'}{2x(2+3x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(4+21x)y'}{2x(2+3x)} + \frac{(9x-1)y}{2x^2(2+3x)} = 0$

☐ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{4+21x}{2x(2+3x)}, P_3(x) = \frac{9x-1}{2x^2(2+3x)}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 1$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{1}{4}$

- ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2(2+3x)\left(\frac{d}{dx}y'\right) + x(4+21x)\,y' + (9x-1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ◦ Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m \cdot \left(\frac{d}{dx}y'\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d}{dx}y'\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+2r)\,(-1+2r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+1)\,(2k+2r-1) + 3a_{k-1}(2k+2r+1)\,(k+r)\right) x^{k+}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(1+2r)\,(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$4\left(k+r+\frac{1}{2}\right)\left(\left(k+r-\frac{1}{2}\right)a_k + \frac{3a_{k-1}(k+r)}{2}\right) = 0$$

- Shift index using $k->k+1$

$$4\left(k+\frac{3}{2}+r\right)\left(\left(k+r+\frac{1}{2}\right)a_{k+1} + \frac{3a_k(k+r+1)}{2}\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{3a_k(k+r+1)}{2k+2r+1}$$

- Recursion relation for $r = -\frac{1}{2}$

$$a_{k+1} = -\frac{3a_k\left(k+\frac{1}{2}\right)}{2k}$$

- Solution for $r = -\frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = -\frac{3a_k\left(k+\frac{1}{2}\right)}{2k}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+1} = -\frac{3a_k\left(k+\frac{3}{2}\right)}{2k+2}$$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{3a_k\left(k+\frac{3}{2}\right)}{2k+2}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = -\frac{3a_k\left(k+\frac{1}{2}\right)}{2k}, b_{k+1} = -\frac{3b_k\left(k+\frac{3}{2}\right)}{2k+2}\right]$$

$$y(x) \to -\frac{3\sqrt{2}c_2 x \operatorname{arctanh}\left(\sqrt{\frac{3x}{2}+1}\right) - 2c_1 x + 2c_2\sqrt{3x+2}}{2\sqrt{x}(3x+2)^{3/2}}$$

1.170 problem 172

Internal problem ID [8308]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 172
Date solved : `Monday, October 21, 2024 at 05:05:40 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(2 + x)\,y' - (2 - 3x)\,y = 0$$

1.170.1 Solved as second order ode using Kovacic algorithm

Time used: 0.294 (sec)

Writing the ode as

$$x^2y'' + \left(x^2 + 2x\right) y' + (3x - 2)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2 + 2x \\ C &= 3x - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 8x + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 8x + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 8x + 8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 324: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{2}{x} + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{2}{x} - \frac{2}{x^2} - \frac{8}{x^3} - \frac{36}{x^4} - \frac{176}{x^5} - \frac{912}{x^6} - \frac{4928}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 8x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-8x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-8x + 8}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -8. Dividing this by leading coefficient in t which is 4 gives -2. Now b can be found.

$$
\begin{aligned}
b &= (-2) - (0) \\
&= -2
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-2}{\frac{1}{2}} - 0\right) &= -2 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-2}{\frac{1}{2}} - 0\right) &= 2
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 8x + 8}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	-2	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 2$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= 2 - (2) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{2}{x} + (-) \left(\frac{1}{2} \right) \\
&= \frac{2}{x} - \frac{1}{2} \\
&= -\frac{x - 4}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r \right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{2}{x} - \frac{1}{2}\right)(0) + \left(\left(-\frac{2}{x^2} \right) + \left(\frac{2}{x} - \frac{1}{2} \right)^2 - \left(\frac{x^2 - 8x + 8}{4x^2} \right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{x} - \frac{1}{2}\right) dx} \\
&= x^2 \mathrm{e}^{-\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x^2 + 2x}{x^2} \, dx} \\
&= z_1 e^{-\frac{x}{2} - \ln(x)} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{2}}}{x} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+2x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-x-2\ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{\mathrm{e}^x}{3x^3} - \frac{\mathrm{e}^x}{6x^2} - \frac{\mathrm{e}^x}{6x} - \frac{\mathrm{Ei}_1(-x)}{6}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(x\,\mathrm{e}^{-x}\right) + c_2 \left(x\,\mathrm{e}^{-x} \left(-\frac{\mathrm{e}^x}{3x^3} - \frac{\mathrm{e}^x}{6x^2} - \frac{\mathrm{e}^x}{6x} - \frac{\mathrm{Ei}_1(-x)}{6}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

1.170.2 Maple step by step solution

Let's solve

$x^2\left(\frac{d}{dx}y'\right) + x(2+x)\,y' - (2-3x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(3x-2)y}{x^2} - \frac{(2+x)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(2+x)y'}{x} + \frac{(3x-2)y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- Define functions

  $\left[P_2(x)=\frac{2+x}{x}, P_3(x)=\frac{3x-2}{x^2}\right]$
- $x\cdot P_2(x)$ is analytic at $x=0$

  $$\left(x\cdot P_2(x)\right)\bigg|_{x=0}=2$$
- $x^2\cdot P_3(x)$ is analytic at $x=0$

  $$\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=-2$$
- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

• Multiply by denominators

$$x^2\left(\frac{d}{dx}y'\right)+x(2+x)\,y'+(3x-2)\,y=0$$

• Assume series solution for y

$$y=\sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m\cdot y$ to series expansion for $m=0..1$

  $$x^m\cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$$
- Shift index using $k->k-m$

  $$x^m\cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$
- Convert $x^m\cdot y'$ to series expansion for $m=1..2$

  $$x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$
- Shift index using $k->k+1-m$

  $$x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$
- Convert $x^2\cdot\left(\frac{d}{dx}y'\right)$ to series expansion

  $$x^2\cdot\left(\frac{d}{dx}y'\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(2+r)\,(-1+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+2)\,(k+r-1)+a_{k-1}(k+r+2)\right)x^{k+r}\right)=0$$

• $a_0$cannot be 0 by assumption, giving the indicial equation

$(2+r)(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 1\}$
- Each term in the series must be 0, giving the recursion relation

  $(k+r+2)(a_k(k+r-1) + a_{k-1}) = 0$
- Shift index using $k- >k+1$

  $(k+r+3)(a_{k+1}(k+r) + a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{k+r}$
- Recursion relation for $r = -2$

  $a_{k+1} = -\frac{a_k}{k-2}$
- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 2$

  $a_{k+1} = -\frac{a_k}{k-2}$
- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a_k}{k+1}$
- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = -\frac{a_k}{k+1}\right]$

1.171 problem 173

Internal problem ID [8309]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 173
Date solved : `Monday, October 21, 2024 at 05:05:41 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2(1+x)\,y''+4x(3+8x)\,y'-(5-49x)\,y=0$$

1.171.1 Solved as second order ode using Kovacic algorithm

Time used: 0.290 (sec)

Writing the ode as

$$\left(4x^3+4x^2\right)y''+\left(32x^2+12x\right)y'+(49x-5)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^3+4x^2 \\ B &= 32x^2+12x \\ C &= 49x-5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-x^2 - 8x + 8}{4\left(x^2 + x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -x^2 - 8x + 8 \\
t &= 4\left(x^2 + x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-x^2 - 8x + 8}{4\left(x^2 + x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 326: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4(1+x)^2} - \frac{6}{x} + \frac{6}{1+x} + \frac{2}{x^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}\end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 8x + 8}{4(x^2+x)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\ \alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{-x^2-8x+8}{4\left(x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right)\\ &= \frac{1}{2}-\left(\frac{1}{2}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{3}{2\left(1+x\right)} + \frac{2}{x} + (-)\left(0\right) \\
&= -\frac{3}{2\left(1+x\right)} + \frac{2}{x} \\
&= \frac{x+4}{2x\left(1+x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{3}{2\left(1+x\right)} + \frac{2}{x}\right)(0) + \left(\left(\frac{3}{2\left(1+x\right)^2} - \frac{2}{x^2}\right) + \left(-\frac{3}{2\left(1+x\right)} + \frac{2}{x}\right)^2 - \left(\frac{-x^2-8x+8}{4\left(x^2+x\right)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{3}{2(1+x)} + \frac{2}{x}\right) dx} \\
&= \frac{x^2}{\left(1+x\right)^{3/2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{32x^2+12x}{4x^3+4x^2}\, dx} \\
&= z_1 e^{-\frac{3\ln(x)}{2} - \frac{5\ln(1+x)}{2}} \\
&= z_1 \left(\frac{1}{x^{3/2}\left(1+x\right)^{5/2}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{(1+x)^4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{32x^2+12x}{4x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-3\ln(x)-5\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{1}{3x^3} + \ln(x) - \frac{3}{2x^2} - \frac{3}{x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x}}{(1+x)^4}\right) + c_2 \left(\frac{\sqrt{x}}{(1+x)^4}\left(-\frac{1}{3x^3} + \ln(x) - \frac{3}{2x^2} - \frac{3}{x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

1.171.2 Maple step by step solution

Let's solve

$4x^2(1+x)\left(\frac{d}{dx}y'\right) + 4x(3+8x)\, y' - (5-49x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d}{dx}y'$

- Isolate 2nd derivative

  $\frac{d}{dx}y' = -\frac{(49x-5)y}{4x^2(1+x)} - \frac{(3+8x)y'}{x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d}{dx}y' + \frac{(3+8x)y'}{x(1+x)} + \frac{(49x-5)y}{4x^2(1+x)} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{3+8x}{x(1+x)}, P_3(x) = \frac{49x-5}{4x^2(1+x)}\right]$
  - $(1+x) \cdot P_2(x)$ is analytic at $x = -1$
    $\left((1+x) \cdot P_2(x)\right)\bigg|_{x=-1} = 5$
  - $(1+x)^2 \cdot P_3(x)$ is analytic at $x = -1$
    $\left((1+x)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$
  - $x = -1$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = -1$
- Multiply by denominators
  $4x^2(1+x)\left(\frac{d}{dx}y'\right) + 4x(3+8x)\,y' + (49x-5)\,y = 0$
- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$
  $(4u^3 - 8u^2 + 4u)\left(\frac{d}{du}\frac{d}{du}y(u)\right) + (32u^2 - 52u + 20)\left(\frac{d}{du}y(u)\right) + (49u - 54)\,y(u) = 0$
- Assume series solution for $y(u)$
  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$
    $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$
  - Shift index using $k- >k-m$
    $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$
    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$
  - Shift index using $k- >k+1-m$
    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$
  - Convert $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$
    $u^m \cdot \left(\frac{d}{du}\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $$u^{m}\cdot\left(\frac{d}{du}\frac{d}{du}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

  Rewrite ODE with series expansions

  $$4a_{0}r(4+r)\,u^{-1+r}+\left(4a_{1}(1+r)\,(5+r)-2a_{0}\left(4r^{2}+22r+27\right)\right)u^{r}+\left(\sum_{k=1}^{\infty}\left(4a_{k+1}(k+1+r)\,(k+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$4r(4+r)=0$$

- Values of r that satisfy the indicial equation

  $$r\in\{-4,0\}$$

- Each term must be 0

  $$4a_{1}(1+r)\,(5+r)-2a_{0}\left(4r^{2}+22r+27\right)=0$$

- Each term in the series must be 0, giving the recursion relation

  $$4a_{k+1}(k+1+r)\,(k+5+r)-2a_{k}\left(4k^{2}+8kr+4r^{2}+22k+22r+27\right)+a_{k-1}(2k+5+2r)^{2}=($$

- Shift index using $k- >k+1$

  $$4a_{k+2}(k+2+r)\,(k+6+r)-2a_{k+1}\left(4(k+1)^{2}+8(k+1)\,r+4r^{2}+22k+49+22r\right)+a_{k}(2k+$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{4k^{2}a_{k}-8k^{2}a_{k+1}+8kra_{k}-16kra_{k+1}+4r^{2}a_{k}-8r^{2}a_{k+1}+28ka_{k}-60ka_{k+1}+28ra_{k}-60ra_{k+1}+49a_{k}-106a_{k+1}}{4(k+2+r)(k+6+r)}$$

- Recursion relation for $r=-4$

  $$a_{k+2}=-\frac{4k^{2}a_{k}-8k^{2}a_{k+1}-4ka_{k}+4ka_{k+1}+a_{k}+6a_{k+1}}{4(k-2)(k+2)}$$

- Series not valid for $r=-4$, division by 0 in the recursion relation at $k=2$

  $$a_{k+2}=-\frac{4k^{2}a_{k}-8k^{2}a_{k+1}-4ka_{k}+4ka_{k+1}+a_{k}+6a_{k+1}}{4(k-2)(k+2)}$$

- Recursion relation for $r=0$

  $$a_{k+2}=-\frac{4k^{2}a_{k}-8k^{2}a_{k+1}+28ka_{k}-60ka_{k+1}+49a_{k}-106a_{k+1}}{4(k+2)(k+6)}$$

- Solution for $r=0$

  $$\left[y(u)=\sum_{k=0}^{\infty}a_{k}u^{k},a_{k+2}=-\frac{4k^{2}a_{k}-8k^{2}a_{k+1}+28ka_{k}-60ka_{k+1}+49a_{k}-106a_{k+1}}{4(k+2)(k+6)},20a_{1}-54a_{0}=0\right]$$

- Revert the change of variables $u=1+x$

  $$\left[y=\sum_{k=0}^{\infty}a_{k}(1+x)^{k},a_{k+2}=-\frac{4k^{2}a_{k}-8k^{2}a_{k+1}+28ka_{k}-60ka_{k+1}+49a_{k}-106a_{k+1}}{4(k+2)(k+6)},20a_{1}-54a_{0}=0\right]$$

1.172 problem 174

Internal problem ID [8310]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 174
Date solved : `Monday, October 21, 2024 at 05:05:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y'' - x(3+10x)\,y' + 30xy = 0$$

1.172.1 Solved as second order ode using Kovacic algorithm

Time used: 0.293 (sec)

Writing the ode as

$$x^2(1+x)\,y'' + \left(-10x^2 - 3x\right)y' + 30xy = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(1+x) \\ B &= -10x^2 - 3x \\ C &= 30x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-48x + 15}{4\left(x^2 + x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -48x + 15$$
$$t = 4\left(x^2 + x\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-48x + 15}{4\left(x^2 + x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 328: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 1\\ &= 3\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 3 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 3 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4x^2} + \frac{39}{2(1+x)} + \frac{63}{4(1+x)^2} - \frac{39}{2x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{63}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{2}\end{aligned}$$
